The establishment of the prefect consists of a numerous body of *commissaires*, inspectors, and peace-officers, in due gradation; and the gendarmerie are at his absolute disposal, who answer the best to the description of the constables of the London central police. It will be observed that the functions of the prefect of Paris and his officers are principally administrative; but they also act judicially, as the French law terms it, to a certain extent, in securing and collecting evidence against such offenders as are amenable to the jurisdiction of the tribunals of correctional police.

H e
po.

The French executive government has long exercised, and still seems to possess the right of exercising what is called the *haute police administrative,* in all cases where an individual has done an act considered by the executive as dangerous to the public safety, although not contrary to the existing law. This is the undefined power that has instituted the odious system of secret police, and has been made the instrument of so much tyranny and injustice. It is, in truth, no part of the established police system, but rather an arbitrary power of *ex post facto* legislation committed to the Government, for supposed cases of danger which the law may not have foreseen. The "haute police administrative" is usually exercised by the Minister of the Interior, through the préfet de police, and occasionally by the Council of State.

The law has, however, clearly defined that department of the Haute Police, which takes under its control offenders discharged from prison, and watches over their conduct for a specified time. This constitutes a part of the punishment to which certain offenders may be sentenced, pursuant to the penal code.[1] It extends to both the higher and lower classes of delinquents. The effect of it is to give to the Government the right to determine certain places in which the offender is forbidden to appear after his discharge from prison. He is, besides, required to declare, before he is set at liberty, in what place he intends to reside; and thereupon he receives an order regulating his route to such place. On his arrival he must present himself within twenty-four hours, before the mayor of the commune, and cannot change his residence without informing the mayor three days beforehand, of the place to which he desires to remove, and receiving from him a new order prescribing his route thither. In case of breach of these regulations, the offender is liable to imprisonment not exceeding five years. The terms of surveillance vary according to the crime; but vagrants and mendicants are specially subjected to a surveillance of not less than five, nor more than ten years.

The provisions of the penal code of France have lately been modified, by dispensing with those enactments which required prisoners, on their discharge, to find security for their good behaviour, and in default assigned them a fixed place of residence. It was found, in practice, that very few indeed were able to find the security, and the restriction of the convict to a particular locality rendered him so notorious as to make it impracticable for him to obtain a livelihood. Some were actually reduced to such destitution as to be under the necessity of begging a temporary admission into prison. We have seen that, at present, the government only reserves the right of prohibiting certain places; and the list of such places comprises, Paris and its suburbs, Lyons, Marseilles, Bordeaux, Lisle, Strasbourg, Nantes, Brest, Toulon, Rochfort, L'Orient, and Cherbourg. Even to these places the convict is allowed access for any special reasons approved by the police. The number of discharged convicts thus under the surveillance of the Haute Police throughout France, was in 1833, about 40,000.[2]

It has has been already suggested, whether a system of police-supervision might not be introduced into the English criminal law with good effect, and, in particular, as a valuable instrument of rural police. The working of the French Haute Police would afford, without doubt, some useful lessons towards fixing the proper limit of restriction. It demonstrates, especially, the wisdom of interfering as little as possible with the market for the labour of the discharged convict; and this is of the more importance in England in proportion to the greater density of population. In the United States, where the demand for labour is boundless, the emancipated convict transports himself to a distance from the seat of his crime, and obtains immediate employment without a stigma on his character. But in England and France the difficulty of earning a livelihood is comparatively so great, that caution is requisite, lest the tendency of any system of police surveillance to be established, should be to abridge the means of subsistence of the criminal population. The difficulty, however, is by no means one against which it seems impracticable to guard successfully.

Prostitution

The French medical police consists of the restrictions imposed by law upon the exercise of the medical profession, and the vending of secret remedies, which are liable to examination before they can be sold. The subject of prostitution belongs also principally to this head.

The law of France visits with punishment "every person who shall have committed a public outrage on modesty."[1] But the law being silent in all such cases of prostitution as do not thus constitute a *public* violation of decency, the administration is placed in the delicate position of having to determine what may amount to such a violation. The police, therefore, whilst it prohibits the open scandal of prostitution; not allowing immodest women to appear in the street, or in public places, or any indecency to be openly committed; acts upon the principle of tolerating houses of debauchery, and preventing by its *surveillance*, as much as possible of the injury arising to the public from such establishments. These houses are therefore licensed, and the number of them in Paris is about 220. Every female living in habitual prostitution is required to be registered by the police. Such as reside at their own houses are obliged to present themselves regularly, at stated periods, at the public dispensary for medical examination; and those inhabiting the *maisons de tolérance*, are also regularly visited by the medical authorities. Every female carries with her a ticket, upon which the medical inspections are noted from time to time. All females known to the police as prostitutes, but unregistered *(insoumises)*, are liable to arrest, and are brought to the dispensary for examination.

[1] Code Pénal, art. 11.

[2] *Circulaire du Ministre de l'Intérieur du* 18 *Juillet* 1833, *sur la Surveillance Légale des Condamnés Libérés;* a document well worthy of reference.

The number of *registered* prostitutes in Paris appears to have gradually increased, from a monthly average of 1293, in the year 1812, to an average of 2902 in the year 1822, and of 3558 in 1832.[2] In the year 1834, the monthly average was 3786.[3] It does not of course follow, that the actual number of prostitutes has increased commensurately with the numbers registered; on the contrary, there is reason to believe it has diminished. But to determine this point accurately, we should have before us the comparative numbers, both registered and unregistered, for a series of years back; which, it would seem, there are no means of ascertaining.

There can be no doubt that the effect of these regulations has operated very beneficially upon the health of the registered prostitutes. It appears that the monthly average of disease amongst the registered women, wherever resident, upon a series of years, from 1812 to 1832, has varied from one in seventeen to one in thirty-four,[4] and that in 1834, it did not exceed one in 43;[5] whilst the proportion of the total number of the unregistered, or *insoumises*, arrested by the police from 1816 to 1828, who were found diseased, was as high as one in four,[4] and upon a monthly average of the year 1834, it was even higher.[5] The police regulations, therefore, confine the existence of disease in a great degree to the class of prostitutes who receive their visitors privately, without any official cognizance. There are no means of knowing the actual extent of licentiousness amongst the female population of Paris; but the police is, of course, not responsible for the disease resulting from it; and although it might be objected that the removal of disease, as a result of prostitution, is a sort of encouragement to immorality, still it must be remembered, that prostitution is, in large towns, an inevitable evil; that it is, to a large class of persons, an industry, and a resource against want; and that, it being wholly out of the power of police regulations to prevent it, the more it can be divested of its power of injuring society physically and morally, the lighter will be the evil of its existence.

Belgium.

In Belgium there is no centralized police, but it is subject to the local authorities. A recent law has placed discharged convicts under the temporary supervision of the police, in the same way as in France.[6]

Police. Prussia.

The police of Prussia is also a matter belonging to separate jurisdictions throughout the kingdom. The *landraths* in the rural districts exercise powers resembling those of our justices of the peace. In the cities special boards are appointed, under the direction of which the regulation of buildings, sewers, and supplies of water and of food are placed.[7] The police superintends the examination of medical practitioners; the insurance offices; and the fire-engines. It exercises the usual functions for the prevention of crimes, and keeps a certain degree of surveillance over vagrants and mendicants. Brothels are subject to visitation, and prostitutes to medical examination. There is no secret system of police in Prussia, analogous to that of France which we have described; nor does it, we believe, now exist, in any part of Germany.

The length at which we have described the police institutions of England and France, will render the less necessary a particular reference to those of the other European states, because little is to be learned from them; and in all countries, the institutions of which are in arrear of civilization, the distinction between police, and other branches of administration, is marked less and less strongly, until we descend to the point of barbarism, at which there is a confusion of all the functions of government, internal and external, civil and military, legislative, judicial, and ministerial, in one absolute sway; with comparatively inadequate security against foreign aggression, and none whatever for domestic peace. A good police system is, on the contrary, a distinguishing mark of the supremacy of organized law in the country where it is in force.

Having thus endeavoured to present such a sketch of existing institutions as our space will admit, it only remains to point out what we consider as the indispensable requisites of a good police system. These are,—

Requisites of a good police system.

1st, Centralization, under one superintending authority, which may keep up a regular and certain channel of communication, throughout every part of the country, may secure uniformity of administration, and enforce vigilance and activity in the officers employed.

2d, The powers and duties of the police force should be so correctly defined, as to leave no room for doubt, when action is required. The whole charge, both of preventing the perpetration of crime, and securing offenders for justice, should be committed to it, with such miscellaneous functions as the legislature may properly entrust to it in addition. No person ought ever to act both ministerially in aid of police, and also judicially as a magistrate.

3d, The utmost care and caution are needful in fixing the extent of police interference, so that the amount of public advantage derivable from it, shall exceed that of the inconvenience sustained. This task is a delicate and difficult one; for police interference has, in some instances, been so wrongly applied as to defeat its own end.

4th, A good system of secondary punishments is essential to the efficiency of a police establishment. If the tendency of imprisonment is such as to excite to crime, it counteracts the most important object of police, namely, its prevention.

Other matters will probably have suggested themselves to the reader; but our limits do not permit us to discuss them at length. The requisites above stated may be considered as cardinal points, which cannot be disregarded without impairing the efficiency of any system of police to which they are wanting.

POLICY of Insurance, or Assurance, of ships, is a contract or convention, by which a person takes upon himself the risks of a sea-voyage; obliging himself to make good in part or in whole the losses and damages that may befall the vessel, its equipage, tackle, victualling, lading, &c. either from tempests, shipwrecks, pirates, fire, war, reprisals, in consideration of a certain sum, more or less, according to the risk; which sum is paid down to the assurer by the assuree upon his signing the policy.

POLIGNA, Melchior de, a French cardinal, was born of an ancient and noble family at Puy, the capital of Velay, in 1662. He was sent by Louis XIV. as ambassador extraordinary to Poland, where, on the death of Sobieski, he formed a project of procuring the election of the prince of Conti; but failing in this, he returned home under some disgrace. When restored to favour, he was sent to Rome as auditor of the Rota. He acted as plenipotentiary during the congress at Utrecht, at which time Clement I. created him cardinal; and upon the accession of Louis XV. he was appointed to reside as minister of France at Rome, where he remained till the year 1732, and died in the year 1741. He left behind him a manuscript poem, entitled *Anti-Lucretius, seu De Deo et Natura*, the plan of which he is said to have formed in Holland in a conversation with Bayle.

POLIGNY, an arrondissement of the department of the Jura, in France, extending over 496 square miles. It comprehends seven cantons, divided into 161 communes, and contains 72,650 inhabitants. The capital is a city of the same name, situated on the river Elantine. It is well built, and in a fertile district, in which some good red wine is produced. It contains 1150 houses, with 5620 inhabitants, who make porcelain, tan leather, and refine much saltpetre.

POLISHER, or Burnisher, amongst mechanics, an instrument for polishing and burnishing things proper to take a polish.

POLITENESS means elegance of manners, or good breeding. Lord Chesterfield denominates it the art of pleasing. It has also been called an artificial good nature; and indeed good nature is the foundation of true politeness, for without it art will make but a very indifferent figure, and generally defeat its own ends. Where compliance and assent, caution and candour, arise from a natural tenderness of disposition and softness of nature, as they sometimes do, they are almost always amiable, and certainly excusable; but as the effects of artifice, they must be despised. The persons who possess them are often indeed themselves dupes of their own deceit, when they imagine others are deluded by it; for excessive art always betrays itself.

A variety of excellent rules for acquiring politeness, with strictures on particular kinds of impoliteness, may be found in the Spectator, Rambler, Idler, Lounger, Mirror, and other periodical works of that kind; in Knox's Essays, and among Swift's works. Chesterfield's Art of Pleasing, and his Letters, are also worthy of perusal, provided the reader be on his guard against the insincerity and the false maxims which these books are calculated to infuse.

POLITIAN, Angelo, was born at Monte Pulciano in Tuscany, in the year 1454. He studied the Greek language, of which he became a complete master, under Andronicus of Thessalonica. He is said to have written verses both in Greek and in Latin when he was not more than twelve years of age. He also studied the Platonic philosophy under Marsilius Ficinus, and that of Aristotle under Argyropylus. Politian was one of the most learned and polite writers of his time. The first work which gained him a reputation was a poem on the tournament of Julian de' Medicis. The account he wrote, some time afterwards, of the conspiracy of the Pazzi, was also very much esteemed. He composed many other pieces which merit approbation; and had he lived longer, he would have enriched the republic of letters with many excellent works. He died at the age of forty. His morals answered the homeliness of his face rather than the beauty of his genius; for Paul Jovius informs us, that he was a man of singularly awkward and perverse manners, of a countenance by no means open and liberal, a nose remarkably large, and squinting eyes. "He was crafty, satirical, and full of inward malice; for his constant way was to sneer and ridicule the productions of other men, and never to allow any criticism, however just, upon his own."

Nevertheless, Politian was a man of consummate erudition; and not only so, but a very polite and elegant writer. Erasmus, in his *Ciceronianus*, calls him a rare miracle of nature, on account of his excelling in every kind of writing. "Fateor angelum prorsus angelica fuisse mente, rarum naturæ miraculum, ad quodcunque scripti genus applicaret animum." Some of his poems were so much admired, that several learned men have made it their business to comment on them. It has often been reported that he spoke of the Bible with contempt; and that, having read it but once, he complained that he had never spent his time so ill. But this is not probable; for it must be remembered that he was a priest and canon of Florence, and we learn from one of his epistles that he preached during a whole Lent. It does not indeed follow from this that he did not think contemptuously of the Bible, because many of his church, especially amongst the better sort, have not been very orthodox believers, and he might be one of these; but it is not likely he would speak out so freely. "I could much more easily believe," says Bayle, "the judgment he is said to have pronounced on the Psalms of David and the Odes of Pindar. He did not deny that there are many good and fine things in the Psalms; but he pretended that the same things appear in Pindar with more brightness and sweetness." The two Scaligers have spoken highly of Politian. The elder has preferred a consolatory elegy of his to that which Ovid sent to Livia upon the death of Drusus, and says he would rather have been the author of it; the younger calls him an excellent poet, but thinks the style of his epistles too inflated and declamatory.

The first edition of the works of Politian is that of Aldus, Venice, 1498, in folio, which was followed by those of Paris, Badius, 1512 and 1519, in the same form, and Lyons, Gryphes, 1528, 1533, and 1545, in two volumes 8vo. But the most complete edition is that which appeared at Basil in 1553, and is the only one that contains the history of the Conspiracy of the Pazzi, which had been published separately in 1472, in 4to, probably at Florence, and which J. Adimari reprinted at Naples in 1769, 4to. The original edition of the *Miscellanea*, Florence, 1489, in folio, is in greater request than those of Brescia, 1496, Venice, 1508, and Basil, 1522, all in folio. The *Stanze* were reprinted at Bologna with the *Orfeo*, 1494, in 4to; and many other editions followed, till 1820, when they were inserted in the *Bibliotheca Poetica Italiana.*

POLITICAL, from πολις, a city, signifies any thing that relates to policy or civil government.

POLITICAL ARITHMETIC is the art of reasoning by figures upon matters relating to government; such as the revenues, number of people, extent and value of land, taxes, trade, &c. in any nation. These calculations are generally made with a view to ascertain the comparative strength, prosperity, and resources of any two or more nations. With this view, Sir William Petty, in his Political Arithmetic, entered into a variety of calculations concerning the different countries of Europe. With these calculations Dr Davenant was dissatisfied; and, therefore, from the observations of Mr Gregory King, he advanced others of his own. (See his Essay on Trade.) The advancement of society has entirely superseded the calculations of these writers; but their works are deserving of notice, as marking the progress of knowledge in this branch of political science. See the articles Insurance, Mortality, and Statistics.

POLITICAL ECONOMY.

Political Economy.

THE subordinate parts of the science of political economy have been treated in separate articles of this work, with the fulness which their importance seemed to require. The present article, therefore, will be principally confined to an attempt to define the objects and limits of the science—to trace its progress—to exhibit and establish the fundamental principles on which it is founded—and to point out the relation and dependence of its different parts. In doing this, we shall have occasion to examine some of the more prominent theories advanced in this field of inquiry; our object being, not merely to lay before the reader what we conceive to be a true theory of the science, but also to present him with as full an exposition as our limits will allow of the doctrines advocated by the more celebrated of its professors.

PART I.

DEFINITION AND HISTORY.

Definition of the Science.—Causes of its being neglected in Greece and Rome, and in the Middle Ages.—Species of Evidence on which its Conclusions are founded.—Rise of the Science in Modern Europe.—Mercantile System.—Progress of Commercial Philosophy in England in the Seventeenth and Eighteenth Centuries.—System of Quesnay and the French Economists.—Publication of the "Wealth of Nations."—Distinction between Politics and Statistics, and Political Economy.

Definition of the science.

Political economy[1] is *the science of the laws which regulate the production, distribution, and consumption of the products necessary, useful, or agreeable to man, which it requires some portion of voluntary labour to produce, procure, or preserve.*

This definition has been framed so as to exclude all reference to articles existing independently of man, and which may be obtained in unlimited quantities without any laborious exertion. Had such been the case with all the articles required to satisfy our wants and desires, this science would either not have existed, or would have been cultivated only as a source of amusement, without any view to utility. Political economy is exclusively conversant with objects which come under the observation of every man, and are continually modified by human interference. It is, in fact, the *science of values;* and nothing destitute of exchangeable value, or which will not be accepted as an equivalent for something else that is either wholly or partially the produce of labour, can come within the scope of its inquiries. It is obvious, however, that an article may be possessed of the highest degree of *utility*, or, as it is sometimes termed, of intrinsic worth, and yet be wholly destitute of value in exchange. Without utility nothing will ever be an object of demand; but how necessary soever any article may be to our comfort, or even existence, and however great the demand for it, still, if it be a spontaneous production of nature, if it exist independently of human agency, and if every individual have an indefinite command over it, it can never become the subject of an exchange, or afford any basis for the reasonings of the economist. It cannot justly be said, that the food with which we appease the cravings of hunger, or the clothes by which we are defended from the inclemency of the weather, are more useful than atmospheric air; and yet they are possessed of that value of which it is totally destitute. The reason is, that food and clothes are not, like air, gratuitous products; they cannot be had at all times without any exertion; they are *obtainable only by labour;* and as none will voluntarily sacrifice the fruits of their industry without an equivalent, they are truly said to possess exchangeable value.

Definitio

Distinc- between value in exchang and utili

The word *value* has, we are aware, been very generally employed to express, not only the exchangeable worth of a commodity, or its capacity to exchange for or buy other commodities, but also to express its *utility*, or its capacity of satisfying our wants, and of contributing to our comforts and enjoyments. But it is obvious that the utility of commodities—that the capacity of bread to appease hunger, or of water to quench thirst—is a totally different and distinct quality from their capacity to exchange for or buy other commodities. Dr Smith perceived this difference, and showed the importance of carefully distinguishing between the utility, or, as he expressed it, the "value in use," of commodities, and their value in exchange. But he did not always keep this distinction in view, and it has been frequently lost sight of by later writers. We have no doubt, indeed, that the confounding of these opposite qualities has been one of the principal causes of the confusion and obscurity in which many branches of the science, not in themselves difficult, are still involved. When it is said that water is highly valuable, the phrase has a very different meaning from what is attached to it when it is said that gold is valuable. Water is indispensable to existence, and has, therefore, a high degree of utility, or of "value in use;" but being generally obtainable in large quantities, without much labour or exertion, it has, in most places, but a very low value in exchange. Gold, on the other hand, is of comparatively little utility; but as it exists only in limited quantities, and as a great deal of labour is necessary to procure it in small supplies, it has a high value in exchange, and will be readily accepted as an equivalent for a large quantity of most other things. To confound these different sorts of value would evidently lead to the most erroneous conclusions. And, therefore, to avoid all chance of error from mistaking the sense of so important a word as *value*, we shall not use it except to signify exchangeable worth, or value in exchange; and shall employ the word *utility* to express the power or capacity of an article to satisfy our wants and desires.

A few words will suffice to show the necessity and importance of distinguishing between utility and value. Were they identical, or were they regulated by the same laws, it would necessarily follow, that whatever increased the utility of any article would also increase its value, and *vice versa.* But the fact is distinctly and completely the reverse. The utility of a commodity is never increased by merely raising its value. A deficient harvest increases the exchangeable value of corn, but most certainly it does not increase its utility. Were such an improvement made in the manufacture of hats as should enable them to be produced for half the expense it now takes to bring them to market, their value, and consequently their price, would very soon be also reduced a half. Each individual would be able to buy two hats for the same sum it formerly required to buy one; and while the utility of no single hat would be impaired by this fall of value, it is plain that the sphere of their utility inition.

---

[1] *Economy*, from οἰκος, *a house*, or *family*, and νομος, *a law—the government of a family.* Hence political economy may be said to be to the state what domestic economy is to a family.

would be greatly extended, and that they would be brought within the reach of a large proportion of those whose poverty might previously have hindered their obtaining them. The grand object, in fact, of this science is to discover the means by which the value of commodities may be reduced to the lowest possible limits. For, the more their value is reduced, the more obtainable they become, and the greater, consequently, is the amount of necessaries, conveniencies, and luxuries at the disposal of every individual.

inition
e term
lth.

Political economy has frequently been defined to be "the science which treats of the production, distribution, and consumption of *wealth*;" and if by wealth be meant those material products which possess exchangeable value, and are necessary, useful, or agreeable to man, the definition is quite unexceptionable. But those who have adopted this definition have attached a different, and a much too extensive, meaning to the term wealth. They have sometimes, for example, considered wealth as synonymous with "*all that man desires as useful and agreeable.*" But if political economy were to embrace a discussion of the production and distribution of all that is useful and agreeable, it would include within itself every other science; and the best Encyclopædia would really be the best treatise on political economy. Good health is useful and delightful, and therefore, on this hypothesis, the science of wealth should comprehend the science of medicine; civil and religious liberty are highly useful, and therefore the science of wealth should comprehend the science of politics; good acting is agreeable, and therefore, to be complete, the science of wealth should embrace a discussion of the principles of the histrionic art, and so on. Such definitions are obviously worse than useless. Their only effect is to generate confused and perplexed notions respecting the objects and limits of the science, and to prevent the student ever acquiring a distinct idea of the nature of the inquiries in which he is engaged.

Mr Malthus defined wealth to consist of "those material objects which are necessary, useful, and agreeable to man." (*Principles of Political Economy*, p. 28.) But waiving the objections that may justly be made to the introduction of the word "material," it is still too comprehensive to be made use of. Atmospheric air, and the heat of the sun, are both material products, and are highly useful and agreeable. But their independent existence, and incapacity of appropriation, exclude them, as has been already seen, from the investigations of this science.

Dr Smith has not explicitly stated the precise meaning he attached to the term wealth; but he most commonly describes it to be "the annual produce of land and labour." It has, however, been justly objected to this definition, that it refers to the sources of wealth before it is known what wealth is, and that it includes all the useless products of the earth, as well as those appropriated and enjoyed by man.

The above definition is not liable to any of these objections. By confining the science to a discussion of the laws regulating "the production, distribution, and consumption of those products which have exchangeable value, and are necessary, useful, or agreeable," we give it a distinct and definite object. When thus properly restricted, the researches of the economist occupy a field which is exclusively his own. He runs no risk of wasting his time in inquiries which belong to other sciences, or in unprofitable investigations respecting the production and consumption of articles which cannot be appropriated, and exist independently of human industry.

Capacity of appropriation is indispensably necessary to constitute wealth. And we shall invariably employ this term to distinguish those products obtainable only by the intervention of human labour, and which consequently may be appropriated by one individual, and consumed exclusively by him. A man is not said to be wealthy because he has an indefinite command over atmospheric air, this being a privilege he enjoys in common with every one else, and which can form no ground of distinction; but he is said to be wealthy, according to the degree in which he can afford to command those necessaries, conveniencies, and luxuries which are not the gifts of nature, but the products of human industry. It must, however, be carefully observed, that although the possession of value be necessary to the existence of wealth, they cannot be confounded without leading to the most erroneous conclusions. Wealth and value are as widely different as utility and value. It is plain that every man will command a much greater quantity of those necessaries and gratifications of which wealth consists, when their value declines, than when it increases. *Wealth and value vary inversely*,—the one increasing as the other diminishes, and diminishing as the other increases. Wealth is greatest where the facility of production is greatest, and value is greatest where the difficulty of production is greatest.

Definition.

Importance of the science.

The science of political economy is exclusively conversant with that class of phenomena which the exertion of human industry exhibits. Its object is to ascertain the means by which this industry may be rendered most productive of the necessaries, luxuries, and enjoyments which form wealth; the laws which determine its distribution among the different classes of society; and how it may be most profitably consumed. To enter into lengthened arguments to prove the importance of a science having such objects in view, would be worse than useless. The consumption of wealth is indispensable to existence; but the eternal law of Providence has decreed that it can only be procured through the intervention of industry—that man must earn his bread in the sweat of his brow. This twofold necessity renders the production of wealth a constant and principal object of the exertions of the vast majority of the human race. It has subdued the natural aversion of man from labour, given activity to indolence, and armed the patient hand of industry with zeal to undertake, and perseverance to overcome, the most difficult and disagreeable tasks. But when wealth is thus necessary, when the desire to acquire it is sufficient to make us submit to the greatest privations, it is plainly impossible to doubt the utility and importance of the science which teaches the modes by which its acquisition may be facilitated, and by which the greatest amount of wealth may be obtained with the least difficulty. There is no class of persons to whom a knowledge of this science can be considered as extrinsic or superfluous. There are some, doubtless, to whom it may be of more advantage than to others; but it is of the utmost consequence to all. The prosperity of individuals, and consequently of nations, does not depend nearly so much on salubrity of climate, or fertility of soil, as on their power to apply labour with perseverance, skill, and judgment. Industry can balance almost every other deficiency. It can render regions naturally inhospitable and unproductive, the comfortable abodes of an intelligent and refined, a crowded and wealthy population; but where it is wanting, the choicest gifts of nature are of no value; and countries possessed of the greatest capabilities of improvement, with difficulty furnish a miserable subsistence to the scanty population of hordes distinguished only by their barbarism and wretchedness.

Causes of the neglect of this science in antiquity and the middle ages.

The possession of wealth being thus necessary to individual existence and comfort, and to the advancement of nations in the career of civilization, it may well excite astonishment that so few efforts should have been made to discover its sources and facilitate its acquisition, and that the study of political economy was not early considered as forming a principal part in a comprehensive system of educa-

Causes of the neglect of Political Economy.

tion. Two circumstances, to which we shall now briefly advert, seem to have been principally instrumental in occasioning the neglect of this science—the institution of domestic slavery in the ancient world, and the darkness of the period when the plan of education in the universities of modern Europe was first organized.

The citizens of Greece and Rome considered it degrading to employ themselves in those occupations which form the principal business of the inhabitants of modern Europe. In some of the Grecian states they were prohibited from engaging in any species of manufacturing or commercial industry; and in Athens and Rome, where this prohibition did not exist, these employments were universally regarded as mean, mercenary, and unworthy of freemen, and were in consequence carried on exclusively by slaves, or the very dregs of the people.[1] Agriculture was treated with more respect. Some of the most distinguished characters in the earlier ages of Roman history had been actively engaged in rural affairs; but notwithstanding their example, in the flourishing period of the republic, and under the emperors, the cultivation of the soil was usually carried on by slaves, belonging to the landlord, and employed on his account. The mass of Roman citizens were either engaged in the military service,[2] or derived a precarious and dependent subsistence from the supplies of corn furnished by the conquered provinces. In such a state of society the relations subsisting in modern Europe between landlords and tenants, and masters and servants, were unknown; and the ancients were in consequence entire strangers to all those interesting and important questions arising out of the rise and fall of rents and wages, which form so important a branch of economical science. The philosophy of the ancient world was also extremely unfavourable to the cultivation of political economy. The luxurious or more refined mode of living of the rich, was regarded by the ancient moralists as an evil of the first magnitude. They considered it as subversive of those warlike virtues, which were the principal objects of their admiration, and in consequence they denounced the passion for accumulation as fraught with the most injurious consequences. It was impossible that this science should become an object of attention to men imbued with such prejudices; or that it should be studied by those who held the objects about which it is conversant in contempt, and spurned the labour by which wealth is produced.

At the establishment of our universities, the clergy being almost the exclusive possessors of the little knowledge then in existence, their peculiar feelings and pursuits naturally exercised a marked influence over the plans of education they were employed to frame. Grammar, rhetoric, logic, school divinity, and civil law, comprised the whole course of study. To have appointed professors to explain the principles of commerce, and the means by which labour might be rendered most effective, would have been considered as equally superfluous and degrading to the dignity of science. The prejudices against commerce, manufactures, and luxury, generated in antiquity, had a powerful influence in the middle ages. None were possessed of any clear ideas concerning the true sources of wealth, happiness, and prosperity. The intercourse between different countries was extremely limited, and was rather confined to marauding excursions, and a piratical scramble for the precious metals, than to a commerce founded on the gratification of real or reciprocal wants.

Causes of the neglect of Political Economy.

These circumstances sufficiently account for the slow progress of this science, and the little attention paid to it, down to a very recent date. And since it became an object of more general attention and liberal inquiry, the opposition between the theories and opinions that have been espoused by the most eminent of its professors—a necessary and inevitable result of its recent cultivation—has proved exceedingly unfavourable to its progress, and generated a disposition to distrust its best established conclusions. This prejudice is, however, extremely ill founded; and notwithstanding the diversity of the theories that have been formed to explain its various phenomena, it undoubtedly admits of as much certainty in its conclusions as any science not exclusively dependent on mere relation. A brief exposition of the principles on which it is founded, and of the mode in which its investigations should be conducted, will evince the correctness of this statement.

Principles of the science. Nature of the evidence on which its conclusions are founded.

Political economy is not a science of speculation, but of fact and experiment. The principles on which the production and accumulation of wealth and the progress of civilization depend, are not the offspring of legislative enactments. Man's existence depends on his exerting himself to produce wealth; and the desire implanted in his breast, of rising in the world and improving his condition, impels him to save and accumulate. The principles which form the basis of this science make, therefore, a part of the constitution of man and of the physical world, and their operations, like those of the mechanical principles, may be traced by the aid of observation and analysis. There is, however, a material distinction between the physical and the moral and political sciences. The conclusions of the former apply in *every* case, while those of the latter apply only in the *majority* of cases. The principles on which the production and accumulation of wealth depend are inherent in our nature, but they do not exercise the same influence over every individual; and the theorist must satisfy himself with framing his rules so as to explain their operation in the majority of instances, leaving it to the sagacity of the observer to modify them so as to suit individual cases. Thus it is an admitted principle in morals, as well as in political economy, that by far the largest proportion of the human race have a much clearer view of what is conducive to their own interests, than it is possible for any other man, or select number of men, to have, and consequently that it is sound policy to allow individuals to follow the bent of their inclination, and to engage in any branch of industry they think proper. This is the general theorem; and it is one which is established on the most comprehensive expe-

---

[1] The force of the prejudices on this head may be learned from the following quotations: "Illiberales autem et sordidi," Cicero says, "questus mercenariorum, omniumque quorum operæ, non quorum artes emuntur. Est enim illis ipsa merces auctoramentum servitutis. Sordidi etiam putandi, qui mercantur a mercatoribus quod statim vendant, *nihil enim proficiunt, nisi admodum mentiantur!* Opificesque omnes in sordida arte versantur, *nec enim quidquam ingenuum potest habere officina*......Mercatura autem, si tenuis est, sordida putanda est; sin autem magna et copiosa, multa undique apportans, multisque sine vanitate impertiens, non est admodum vituperanda." (*De Officiis*, lib. i. sect. 42.)

"Vulgaris opificum, quæ manu constant, et ad instruendam vitam occupatæ sunt; in quibus nulla decoris, nulla honesti simulatio est." (Senecæ *Epistolæ*, ep. 89.)

A hundred similar quotations might be produced; but the one from Cicero is sufficient to establish the accuracy of what has been advanced. The strength of the prejudice against commerce and the arts is proved by its exerting so powerful an influence over so cultivated a mind. For a further discussion of the opinions of the Romans on this subject, see the *Dissertazione del Commercio de Romani* of Mengotti, which received a prize from the Academy of Paris in 1787, and the *Memoria Apolegetica del Commercio de Romani* of Torres, published at Venice in 1788.

[2] "Rei militaris virtus præstat cæteris omnibus; hæc populo Romano, hæc huic urbi æternam gloriam peperit." (Cicero *pro Murena*.)

rience. It is not, however, like the laws which regulate the motions of the planetary system, universally applicable; it will hold good in nineteen out of twenty instances, but the twentieth may be an exception. But it is not required of the economist that his theories should quadrate with the peculiar bias of a particular person. His conclusions are drawn from contemplating the principles found to determine the condition of mankind, as presented on the large scale of nations and empires. His business is with man in the aggregate, with states, and not with families, with the passions and propensities which actuate the great bulk of the human race, and not with those which are occasionally found to influence a solitary individual.

This distinction should be kept constantly in view. Nothing is more common than to hear it objected to some of the best established truths in political and economical science, that they are at variance with certain facts, and that therefore they should be rejected. But these objections very often originate in an entire misapprehension of the nature of the science. It would be easy to produce a thousand instances of individuals who have been enriched by monopolies and restrictions, and even by robbery and plunder; though it would certainly be rather rash thence to conclude that society may be enriched by such means! This, however, is the single consideration to which the economist has to attend; and, until it can be shown that monopolies and restrictions are not destructive of national wealth, and that what is gained by the monopolist is not lost by the public, he is justified in considering them injurious. To arrive at a well-founded conclusion in this science, it is not enough to observe results in particular cases, or as they affect a few individuals; we must further inquire whether these results be constant and universally applicable,—whether the same circumstances which have given rise to them in one instance, would in every instance, and in every state of society, be productive of the same or similar results. A theory inconsistent with a uniform and constant fact, must be erroneous; but the observance of a particular result at variance with customary experience, and when we may not have the means of discriminating the circumstances attending it, should not make us hastily modify or reject a principle which accounts satisfactorily for the greater number of appearances.

The example of the few arbitrary princes, distinguished by their equity, humanity, and generosity, is not enough to overthrow the principle which teaches that it is of the essence of irresponsible power to debauch and vitiate its possessors, to render them haughty, cruel, and suspicious; nor is the example of those who, attentive only to present enjoyment and careless of the future, lavish their fortune in boisterous dissipation or vain expense, sufficient to invalidate the general conclusion, that the passion for accumulation is stronger and more powerful than the passion for expense. Had this not been the case, mankind could never have emerged from the condition of savages. The stupendous improvements made in different ages and nations, the forests that have been cut down, the marshes and lakes that have been drained and cultivated, the harbours, roads, and bridges that have been constructed, the cities and edifices that have been raised, are *all* the fruit of a saving of income, and establish, in despite of a thousand instances of prodigality, the ascendency and superior force of the accumulating principle.

The want of attention to these considerations has occasioned much of the error and misapprehension with which this science has been and still is infected. Almost all the absurd theories and opinions which have successively appeared have been supported by an appeal to facts. But a knowledge of facts, without a knowledge of their mutual relation, without being able to show why the one is a cause and the other an effect, is, to use the illustration of M. Say, no better than the indigested erudition of an almanac maker, and affords no means of judging of the truth or falsehood of a general principle.

Rise of the
Science in
Modern
Europe.

But, though we are not to reject a received principle because of the apparent opposition of a few results, with the circumstances of which we are unacquainted, we should have no confidence in its solidity, unless it be deduced from a very comprehensive and careful induction. He who would arrive at a true knowledge of the laws regulating the production, distribution, and consumption of wealth, must draw his materials from a very wide surface; he should study man in every different situation—should have recourse to the history of society, arts, commerce, and civilization, to the works of philosophers and travellers, to everything, in short, that can throw light on the causes which accelerate or retard the progress of civilization. He should observe the changes which have taken place in the fortunes and condition of the human race in different regions and ages of the world; should trace the rise, progress, and decline of industry; and, above all, he should carefully discriminate the effect of different political measures, and the various circumstances wherein an advancing and declining society differ from each other. Such investigations, by disclosing the real causes of national opulence and refinement, and of poverty and degradation, furnish the means of satisfactorily solving almost all the important problems in the science of wealth, and of devising a scheme of public administration calculated to insure the continued advancement of society in the career of improvement.

It should be kept in mind, that it is no part of the business of the economist to inquire into the means by which individual fortunes may be increased or diminished, except to ascertain their general operation and effect. The *public interests* should always form the exclusive objects of his attention. He is not to frame systems, and devise schemes, for increasing the wealth and enjoyments of particular classes; but to apply himself to discover the sources of national wealth, and universal prosperity, and the means by which they may be rendered most productive.

Those who reflect on the variety and extent of the previous knowledge required for the construction of a sound theory of political economy, will cease to feel any surprise at the errors into which economists have been betrayed, or at the discrepancy of the opinions still entertained on some important points. This science is of very recent origin. Though various treatises of considerable merit had previously appeared on some of its separate parts, it was not treated as a whole, or in a scientific manner, until about the middle of last century. This circumstance is of itself enough to account for the number of erroneous systems that have since appeared. Instead of deducing their general conclusions from a comparison of particular facts, and a careful examination of the phenomena attending the operation of different principles, and of the same principles under different circumstances, the first cultivators of almost every branch of science begin by framing their theories on a very narrow and insecure basis. Nor is it really in their power to go to work differently. Observations are scarcely ever made or particulars noted for their own sakes. It is not till they begin to be in request as furnishing the only test by which to ascertain the truth of some popular theory, that they are made in sufficient numbers and with sufficient accuracy. It is, in the peculiar phraseology of this science, the *effectual demand* of the theorist that occasions the production of the facts or raw materials he is afterwards to work into a system. The history of political economy strikingly exemplifies the truth of this remark. Being, as already observed, entirely unknown to the ancients, and but little attended to by our ancestors down to a comparatively late period, those circumstances which would have enabled us to judge with the greatest precision, of the wealth and civilization of the more celebrated states of antiquity, and of Europe during the middle ages, have either been thought unworthy of notice by the historian, or have been very imperfectly and carelessly detailed. Those, therefore, who first began to trace the principles of the science had but a comparatively scanty experience on which to build their conclusions. Nor did they even avail themselves of the few historical facts with which they might easily have become acquainted, but almost exclusively confined their attention to those which happened to fall within the sphere of their own observation.

Mercantile system.

Agreeably to what has now been stated, we find that the theories advanced by the early economical writers were formed on the most contracted basis, and were only fitted to explain a few of the most obvious and striking phenomena. The *mercantile theory*, for example, was entirely bottomed on the popular and prevalent opinions respecting money. The precious metals having been long used, both as standards by which to ascertain the comparative value of different commodities, and as the equivalents for which they were most frequently exchanged, acquired a fictitious importance, not merely in the estimation of the vulgar, but in that of persons of the greatest discernment. The simple consideration, that all buying and selling is really nothing more than the bartering of one commodity for another—of a certain quantity of corn or wool, for example, for a certain quantity of gold or silver, and *vice versa*, was entirely overlooked. The attention was gradually transferred from the money's worth to the money itself; and the wealth of individuals and of states came to be measured, not by the abundance of their disposable products,—by the quantity or value of the commodities with which they could afford to purchase the precious metals,—but by the quantity of these metals actually in their possession. It is on this flimsy and fallacious hypothesis that the theories of almost every writer on economical subjects antecedent to the appearance of the works of Child, North, and Locke, in England, and of Gournay and Quesnay in France, are founded; and, what is of infinitely greater moment, it is on this same hypothesis that the different civilized countries have proceeded to regulate their intercourse with each other. Their grand object has not been to facilitate the production of necessaries, comforts, and luxuries, but to monopolize the largest possible supply of gold and silver. And, as these could not be obtained in countries destitute of mines, except in exchange for exported commodities, various schemes were resorted to for encouraging exportation, and for preventing the importation of most products other than the precious metals. In consequence, the excess of the value of the exports over that of the imports was long considered as the most infallible test of the progress of a country in the career of wealth. This excess, it was believed, could not be balanced otherwise than by an equivalent importation of gold or silver, that is, of the only real wealth it was then supposed a country could possess.

These principles and conclusions, though absolutely false and erroneous, afford a tolerable explanation of a few very obvious phenomena, and are in perfect unison with the popular prejudices on the subject. It was natural, therefore, that they should be espoused by the merchants or practical men, who were the earliest writers on this science. They did not consider it necessary to subject the principles they assumed to any refined analysis or examination. But, reckoning them as sufficiently established by the common consent and agreement of mankind, they applied themselves exclusively to the discussion of the practical measures calculated to give them the greatest efficacy.

Balance of trade.

"Although a kingdom," says one of the earliest and ablest writers in defence of the mercantile system, "may be enriched by gifts received, or by purchase taken, from some other nations, yet these are things uncertain, and of small consideration when they happen. The ordinary means, therefore, to increase our wealth and treasure, is by foreign trade, wherein we must ever observe this rule,—to sell more to strangers yearly than we consume of theirs in value. For, suppose, that when this kingdom is plentifully served with cloth, lead, tin, iron, fish, and other native commodities, we do yearly export the overplus to foreign countries to the value of L.2,200,000, by which means we are enabled, beyond the seas, to buy and bring in foreign wares for our use and consumption to the value of L.2,000,000: By this order duly kept in our trading, we may rest assured that the kingdom shall be enriched yearly L.200,000, which must be brought to us as so much treasure; because that part of our stock which is not returned to us in wares, must necessarily be brought home in treasure." (Mun's *Treasure by Foreign Trade*, orig. ed. p. 11.)

The gain on our foreign commerce is here supposed to consist exclusively of the gold and silver which, it is taken for granted, must necessarily be brought home in payment of the excess of exported commodities. Mun lays no stress whatever on the circumstance of foreign commerce enabling us to obtain an infinite variety of useful and agreeable products, which it would either be impossible to produce at all, or to produce so cheaply, at home. We are desired to consider all this accession of wealth,—all the vast addition made by commerce to the motives which stimulate, and to the comforts and enjoyments which reward, the labour of the industrious, as *nothing*, and to fix our attention exclusively on the balance of L.200,000 of gold and silver! This is much the same as if we were desired to estimate the comfort and advantage derived from a suit of clothes, by the number and glare of the metal buttons by which they are fastened! And yet this rule for estimating the advantageousness of foreign commerce was long regarded by the generality of merchants and practical statesmen as infallible; and, until very recently, we were annually congratulated on the excess of our exports over our imports!

Manufa turing tem.

But there were other circumstances, besides the erroneous notions respecting the precious metals, which led to the establishment of the mercantile system, and to the enacting of regulations restrictive of the freedom of industry. The feudal governments established in the countries that had formed the western division of the Roman empire, early degenerated into a system of anarchy and lawless oppression. The princes, unable of themselves to restrain the usurpations of the greater barons, or to control their violence, endeavoured to strengthen their influence and consolidate their power by attaching the inhabitants of cities and towns to their interests. For this purpose, they granted them charters, enfranchising the citizens, abolishing every existing mark of servitude, and forming them into corporations, or bodies politic, to be governed by councils and magistrates of their own selection. The order and good government that were thus established in the cities, and the security enjoyed by their inhabitants, when the rest of the country was a prey to rapine and disorder, stimulated their industry, and gave them a vast ascendency over the cultivators of the soil. It was from them that the princes derived the greater part of their supplies of money; and it was by means of their co-operation that they were enabled to control and subdue the pride and independence of the barons. But the citizens did not render this assistance to their sovereigns merely by way of compensation for the original gift of their charters. They were continually soliciting and obtaining new privileges. And it was not to be expected that princes, whom they had laid under essential obligations, and who must have regarded them as forming by far the most industrious and deserving portion of their subjects, should be at all disinclined to gratify their wishes.

To enable them to obtain their provisions cheap, and to carry on their industry to the best advantage, the exportation of corn, and of the raw materials of their manufactures, was strictly prohibited; at the same time that heavy duties and absolute prohibitions were interposed to prevent the importation of manufactured articles from abroad, and to secure the monopoly of the home market to the native manufacturers. These, together with the privilege granted to the citizens of corporate towns, of preventing any individual from exercising any branch of business without leave from them, and a variety of subordinate regulations intended to force the importation of the raw materials required in manufactures, and the exportation of the manufactured goods, form the principal features of the system of public economy adopted, in the view of encouraging manufacturing industry, in every country of Europe, in the fourteenth, fifteenth, sixteenth, and seventeenth centuries. The freedom of industry recognised by their ancient laws was almost totally destroyed. It would be easy to mention a thousand instances of the excess to which this artificial system was carried in England and other countries; but as many of these must be familiar to the reader, we shall only observe, as illustrative of its spirit, that by an act passed in 1678, for the encouragement of the English woollen manufacture, it was ordered that all *dead bodies* should be wrapped in woollen shrouds!

But the exclusion of foreign competition, and the monopoly of the home-market, did not satisfy the manufacturers and merchants. Having obtained all the advantage they could from the public, they attempted to prey on each other. Those possessed of most influence, procured the privilege of carrying on particular branches of industry, to the exclusion of every one else. This abuse was carried to a most oppressive height in the reign of Elizabeth, who granted an infinite number of new patents. At length the grievance became so intolerable as to make all classes join in petitioning for its abolition; and this, after much opposition on the part of government, who regarded the power of erecting monopolies as a very valuable branch of the prerogative, was effected by an act passed in the 21st of James I. But this act did not touch any of the fundamental principles of the mercantile or manufacturing system; and the exclusive privileges of all bodies corporate were exempted from its operation.

In France the interests of the manufacturers were warmly espoused by Colbert, the justly celebrated minister of finance during the most splendid period of the reign of Louis XIV.; and the year 1664, when the tariff, compiled under Colbert's direction, was promulgated, has been sometimes considered, though improperly, as the æra of the manufacturing system.

These restrictions were zealously supported by the writers in defence of the mercantile system and the balance of trade. The facilities given to the exportation of manufactured goods, and the obstacles thrown in the way of their importation, seemed to them to be particularly well fitted for making the exports exceed the imports, and procuring a favourable balance. Instead, therefore, of regarding these regulations as the offspring of a selfish monopolizing spirit, they looked on them as having been dictated by the soundest policy. The manufacturing and mercantile systems were thus naturally blended together. The acquisition of a favourable balance of payments was the grand object to be accomplished; and heavy duties and restrictions on importation from abroad, and bounties and premiums on exportation from home, were the means by which it was to be attained! It cannot excite surprise that a system having so many popular prejudices in its favour, and which afforded a plausible and convenient apology for the exclusive privileges enjoyed by the manufacturing and commercial classes, should have early attained, or that it should still preserve, notwithstanding the overthrow of its principles, a powerful practical influence. Melon and Forbonnais in France—Genovesi in Italy—Mun, Sir Josiah Child, Dr Davenant, the authors of the British Merchant, and Sir James Steuart, in England—are the ablest writers who have espoused, some with more and some with fewer exceptions, the leading principles of the mercantile system.

"It is no exaggeration to affirm, that there are but few political errors which have produced more mischief than the mercantile system. Armed with power, it commanded and forbid where it should only have *protected.* The regulating mania which it inspired tormented industry in a thousand ways, to force it from its natural channels. It made each nation regard the welfare of its neighbours as incompatible with its own; hence the reciprocal desire of injuring and impoverishing each other; and hence that spirit of commercial rivalry which has been the immediate or remote cause of the greater number of modern wars. This system stimulated nations to employ force or cunning to extort commercial treaties, productive of no real advantage to themselves, from the weakness or ignorance of others. It formed colonies that the mother country might enjoy the monopoly of their trade, and force them to resort exclusively to her markets. In short, where it has been productive of the least injury, it has retarded the progress of national prosperity; everywhere else it has deluged the earth with blood, and has depopulated and ruined some of those countries whose power and opulence it was supposed it would carry to the highest pitch." (Storch, *Traité d'Economie Politique*, tome i. p. 122.)

Progress of commercial science in England.

The greater attention which began to be paid, in the seventeenth, and in the earlier part of the last century, to subjects connected with finance, commerce, and agriculture, gradually prepared the way for the downfall of the mercantile system. The English writers preceded those of every other country, in pointing out its defects, and in discovering the real nature and functions of money, and the true principles of commerce. The establishment of a direct intercourse with India did much to accelerate the progress of sound opinions. Until very recently the precious metals have always been one of the most advantageous articles of export to the East.[1] And when the East India Company was established in 1600, power was given them annually to export *foreign* gold coins or bullion, of the value of L.30,000; the Company being bound to import, within six months after the termination of every voyage, except the first, as much gold and silver as should together be equal to the value of the silver they exported. But the Company's enemies contended that these regulations were not complied with, and that it was contrary to all principle, and highly injurious to the public interests, to permit the exportation of any quantity of bullion. The merchants and others interested in the India trade, among whom we have to reckon Sir Dudley Digges, whose defence of the Company was published in 1615, Mr Mun, who published a very able pamphlet in defence of the Company in 1621,[2] Mr Misselden, and more recently Sir Josiah Child, could not controvert the reasoning of their opponents, without openly impugning some of the commonly received opinions regarding money. In such circumstances it is easy to see that prejudice would be forced to give way to interest. At first, however, the advocates of the Company did not contend, nor is there, indeed, any good reason for thinking that they were of opinion, that the exportation of gold or silver to the East Indies was beneficial, on the ground that the commodities brought back were of greater value. They contended that the Company did not export a greater quantity of bullion than their charter authorized; and they further contended that this exportation was advantageous, because the commodities imported from India were chiefly re-exported to other countries, whence a greater quantity of bullion was obtained in exchange for them.[1] But even this was an immense advance in the progress to a sounder theory. *C'est toujours le premier pas qui coute.* The advocates of the Company began gradually to assume a higher tone; and at length boldly contended that bullion was *nothing but a commodity*, and that its exportation should be as free as that of anything else. Nor were these opinions confined to the partners of the East India Company. They were gradually communicated to others; and many eminent merchants were taught to look with suspicion on several received maxims, and were in consequence led to acquire more correct and comprehensive views regarding commercial intercourse. The new ideas ultimately made their way into the House of Commons; and in 1663 the statutes prohibiting the exportation of foreign coin and bullion were repealed, and full liberty given to the East India Company and to private traders to export them in unlimited quantities.

---

[1] Pliny, when enumerating the spices, silks, and other eastern products imported into Italy, says, "Minimaque computatione millies centena millia sestertium annis omnibus, India et Seres, peninsulaque illa (Arabia) imperia nostro demunt." (*Hist. Nat.* lib. xii. cap. 18.)

Charles V. used to say that the Portuguese, who then engrossed almost the whole commerce of the East, were the common enemies of Christendom, inasmuch as they drained it of its treasure to export it to infidels! (Misselden on *Free Trade*, p. 24.)

[2] This pamphlet, which is now become extremely rare, is printed in Purchas's Pilgrims, vol. i. p. 732.

In addition to the controversies respecting the East India trade, the foundation of the colonies in America and the West Indies, the establishment of a compulsory provision for the support of the poor, and the acts prohibiting the exportation of wool and the non-importation of Irish cattle, &c. drew an extraordinary portion of the public attention to questions connected with the domestic policy of the country. In the course of the seventeenth century, a more than usual number of tracts were published on commercial and economical subjects. And although the doctrines of the greater number are strongly tinctured with the prevailing spirit of the age, it cannot be denied that several of their authors rose far above the prejudices of their contemporaries, and have an unquestionable right to be regarded as the founders of the modern theory of commerce; as the earliest teachers of those sound and liberal doctrines, by which it has been shown that the prosperity of states can never be promoted by restrictive regulations, or by the depression of their neighbours—that the genuine spirit of commerce is inconsistent with the selfish and shallow policy of monopoly—and that the *self-interest* of mankind, not less than their duty, requires them to live in peace, and to cultivate friendship with each other.

Mr Mun.

We have already referred to Mun's treatise entitled England's Treasure by Foreign Trade. This treatise was first published in 1664; but there is good reason to suppose that it had been written many years previously. Mr Mun's son, in the dedication to Lord Southampton, prefixed by him to the work, says that his father "was, *in his time*, famous among merchants," a mode of expression which he would hardly have used had not a considerable period elapsed since his father's death; and Misselden, in his Circle of Commerce, published in 1623 (p. 36), refers to Mun's tract on the East India trade, and speaks of its author as being an accomplished and experienced merchant. Perhaps, therefore, we shall not be far wrong if we assume that the treatise on Foreign Trade was written so early as 1635 or 1640. At all events, it is certain that the doctrines which it contains do not differ much from those which he had previously maintained in his pamphlet in defence of the East India Company, and some of the expressions are literally the same with those of the petition presented by that body to parliament in 1628, which is known to have been written by Mr Mun.[2] The extract we have previously given shows, that Mun's opinions, in so far as regards the question respecting the balance of trade, were identical with those of his contemporaries. But we believe he was the first who endeavoured to show, and who, in point of fact, successfully showed, that a favourable balance could not be procured by restrictive regulations; that the exportation and importation of bullion, coin, and every other commodity, should be freely permitted; and that violent measures will never bring gold or silver into a kingdom, or retain them in it. (Pp. 27, 92, &c. original ed.) Mun also distinctly lays it down, "that those who have wares cannot want money," and that "it is not the keeping of our money in the kingdom, but the necessity and use of our wares in foreign countries, and our want of other commodities, that causeth the vent and consumption on all sides, which causeth a quick and ample trade." (P. 43.)[3] Nor are these detached and incidental passages thrown out at random. They breathe the same spirit which pervades the rest of Mun's book, and constitute and form a part of his system. His observations in answer to Malyne's, on some rather difficult questions connected with exchange, are both accurate and ingenious.

Sir Jos Child.

The first edition of Sir Josiah Child's celebrated work on trade (A New Discourse of Trade, &c.) was published in 1668; but it was very greatly enlarged in the next edition, published in 1690. There are many sound and liberal doctrines advanced in this book. The argument to show that colonies do not depopulate the mother country, is as conclusive as if it had proceeded from the pen of Mr Malthus; and the just and forcible reasoning in defence of the naturalization of the Jews is highly creditable to the liberality and good sense of the writer, and discovers a mind greatly superior to existing prejudices. Sir Josiah has also many judicious observations on the bad effects of the laws against *forestalling* and *regrating*, on those limiting the number of apprentices, and on corporation privileges.

When treating of the laws relating to the exportation of wool, Sir Josiah lays it down as an axiom, "that they that can give the best price for a commodity shall never fail to have it by one means or other, notwithstanding the opposition of any laws, or interposition of any power by sea or land; of such force, subtilty, and violence, is the general course of trade."

The radical defect of Sir Josiah Child's treatise consists in its being chiefly written to illustrate the advantages which he labours to show would result from reducing the legal rate of interest to four per cent.; an error into which he was led by mistaking the low interest of Holland for the principal cause of her wealth, when it was in truth the effect of her comparatively heavy taxation.

It is, however, worthy of remark, that this error was very soon detected. In the same year (1668) that Sir Josiah's treatise first appeared, a tract was published, entitled Interest of Money mistaken, or a treatise proving that the Abatement of Interest is the Effect, and not the Cause, of the Riches of a Nation. The author of this tract maintains the opinion afterwards held by Locke and Montesquieu, that the interest of money does not depend on statutory regulations, but that it varies according to the comparative opulence of a country; or rather according to the scarcity and abundance of money, increasing when the supply of money diminishes, and diminishing when it increases.[1] Having endeavoured to establish this principle, the author successfully contends that Sir Josiah Child had totally mistaken the cause of the wealth of the Dutch, of which he shows the lowness of interest was merely a consequence.

[2] This petition, and the reasons on which it is founded, were so well esteemed as to occasion its being reprinted in 1641.

[3] These expressions are in the petition of the Company, presented to parliament in 1628.

Si William
P 's Po-
lit l Ana-
to .

In 1672 Sir William Petty published his celebrated tract entitled the Political Anatomy of Ireland. In this work, the absurdity of the act passed in 1664, prohibiting the importation of cattle, beef, &c. from Ireland into Britain, is ably exposed, and the advantage of an unconstrained internal commerce clearly set forth. "If it be good for England," says Sir William, "to keep Ireland a distinct kingdom, why do not the predominant party in parliament, suppose the western members, make England beyond Trent another kingdom, and take tolls and customs upon the borders? Or why was there ever any union between England and Wales? And why may not the entire kingdom of England be further cantonised for the advantage of all parties?" (P. 34, ed. 1719.)

The great defect in the writings of Mun, Misselden, Child, and others, does not consist so much in their notions about the superior importance of the precious metals, or the balance of trade, as in those respecting the advantages they supposed were derivable from importing durable rather than rapidly perishable commodities and luxuries. This, however, was an extremely natural opinion; and we need not be surprised that the early writers on commerce fell into an error, from which neither the profound sagacity of Locke, nor the strong sense of Mr Harris, has been able to preserve them. But even so early as 1677, the fallacy of this opinion was perceived. In that year there appeared a small tract, entitled England's Great Happiness; or, a Dialogue between Content and Complaint; in which the author contends, that if there be a demand for wine, fruit, and such like articles, their importation in exchange for money is advantageous; and, on this ground, he defends the French trade, which was loudly declaimed against by the practical men of that day. We shall make a short extract from this remarkable tract:

"*Complaint.*—You speak plain; but what think you of the French trade, which draws away our money by wholesale? Mr Fortrey,[2] whom I have heard you speak well of, gives an account that they get L.1,600,000 a year from us.

"*Content.*—'Tis a great sum; but, perhaps, were it put to a vote in a *wise council*, whether for that reason the trade should be left off, 'twould go *in the negative*. For paper, wine, linen, Castile soap, brandy, olives, capers, prunes, kid-skins, taffaties, and such like, we cannot be without; and for the rest, which you are pleased to style *Apes* and *Peacocks* (although wise Solomon ranked them with gold and ivory), they set us all agog, and have increased among us many considerable trades......I must confess, I had rather they'd use our goods than money; but if not, I would not lose the getting of ten pound because I can't get an hundred; and I don't question but when the French get more foreign trade, they'll give more liberty to the bringing in foreign goods. I'll suppose John-a-Nokes to be a butcher, Dick-a-Styles to be an exchange man, yourself a lawyer; will you buy no meat or ribbands, or your wife a fine Indian gown or fan, because they will not truck with you for indentures which they have need of? I suppose no; but if you get money enough of others, you care not though you give it away in specie for these things. I think 'tis the same case."

The spirit of this tract may perhaps be better inferred from the titles of some of the dialogues. Among others, we have "To export money our great advantage;"—"The French trade a profitable trade;"—"Variety of wares for all markets, a great advantage;"—"High living, a great improvement to the arts;"—"Invitation of foreign arts, a great advantage;"—"Multitudes of traders, a great advantage," &c. &c. But its influence was far too feeble to arrest the current of popular prejudice. In the year after its publication (1678) the importation of French commodities was prohibited for three years. This prohibition was made perpetual in the reign of William III. when the French trade was declared to be a nuisance!—a principle, if we may so call it, which has been acted upon down almost to this very hour.

In 1681 a pamphlet was published in defence of the East India Company, under the signature of "Philopatris," but evidently the production of Sir Josiah Child. In the introduction to this pamphlet the following principles are laid down:—

"That all close monopolies (Sir Josiah contends that the East India Company does not come under this description), of what nature or kind soever, are destructive to trade, and consequently obstructive to the increase of the value of our lands."

"That silver or gold, coined or uncoined, though they are used for a measure of all other things, are no less a commodity than wine, oil, tobacco, cloth, or stuffs; and may, in many cases, be exported as much to the national advantage as any other commodity."

"That no nation ever was, or will be, considerable in trade, that prohibits the exportation of bullion." (P. 3.)

Sir William Petty's *Quantulumcunque.*

In Sir William Petty's *Quantulumcunque*, published in 1682, the subject of money is treated with great ability, and the idea of draining England of her cash, by an unfavourable balance, successfully combated. "If some English merchants," it is said, "should be so improvident as to carry out money only, then the foreign merchants would buy up such English commodities as they wanted with money brought into England from their respective countries, or with such commodities as England likes better than money; for the vending of English commodities doth not depend on anything else but the use and need which foreigners have of them." Sir W. denies that "a country is the poorer for having less money;" and concludes by strongly condemning the laws regulating the rate of interest; observing, that there may as well be laws to regulate the rate of exchange and of insurance. (See pp. 3, 6, 8, original edition.)

Sir Dudley North.

But a tract entitled Discourses on Trade, principally directed to the Cases of Interest, Coinage, Clipping, and Increase of Money, written by Sir Dudley North, and published in 1691, unquestionably contains a far more able statement of the true principles of commerce than any that had then appeared.

---

[1] It has been generally supposed that Hume was the first who showed (in his Essay on Interest) the fallacy of this opinion, and who proved that the rate of interest does not depend on the abundance or scarcity of money, but on the abundance or scarcity of disposable capital compared with the demands of the borrowers, and the rate of profit. This, however, is a mistake, the doctrine in question having been fully demonstrated in a pamphlet written by Mr Massie, entitled Essay on the Governing Cause of the Natural Rate of Interest, published two years before Mr Hume's Essay appeared.

[2] Mr Fortrey's pamphlet has been much referred to. It was published in 1663, and reprinted in 1673. It contains a very good argument in favour of enclosures. The reference in the text sufficiently explains the opinions of the writer in regard to commerce.

We regret that our limits will not permit our giving so full an account as we could have wished of this extraordinary tract. The author is a most intelligent and consistent advocate of the great principles of commercial freedom. He is not, like the most eminent of his predecessors, well informed on one subject, and erroneous on another. He is throughout sound and liberal. His system is consentaneous in its parts, and complete. He shows, that in commercial matters, nations have the same interests as individuals; and exposes the absurdity of supposing that any trade advantageous to the merchant can be injurious to the public. His opinions respecting the imposition of a seignorage on the coinage of money, and the expediency of sumptuary laws, then in great favour, are equally enlightened.

We subjoin from the preface to this tract an abstract of the general propositions maintained in it:

"That the whole world as to trade is but as one nation or people, and therein nations are as persons.

"That the loss of a trade with one nation is not that only, separately considered, but so much of the trade of the world rescinded and lost; for all is combined together.

"That there can be no trade unprofitable to the public; for if any prove so, men leave it off; and wherever the traders thrive, the public, of which they are a part, thrive also.

"That to force men to deal in any prescribed manner, may profit such as happen to serve them; but the public gains not, because it is taking from one subject to give to another.

"That no laws can set prices in trade, the rates of which must and will make themselves. But when such laws do happen to lay any hold, it is so much impediment to trade, and therefore prejudicial.

"That money is a merchandise, whereof there may be a glut, as well as a scarcity, and that even to an inconvenience.

"That a people cannot want money to serve the ordinary dealing, and more than enough they will not have.

"That no man will be the richer for the making much money, nor have any part of it, but as he buys it for an equivalent price.

"That the free coynage is a perpetual motion found out, whereby to melt and coyn without ceasing, and so to feed goldsmiths and coyners at the public charge.

"That debasing the coyn is defrauding one another, and to the public there is no sort of advantage from it; for that admits no character or value but intrinsick.

"That the sinking by alloy or weight is all one.

"That exchange and ready money are the same, nothing but carriage and re-carriage being saved.

"That money exported in trade is an increase to the wealth of the nation; but spent in war, and payments abroad, is so much impoverishment.

"In short, that all favour to one trade or interest is an abuse, and cuts so much of profit from the public."

Unluckily this admirable tract never obtained any considerable circulation. There is good reason, indeed, to suppose that it was designedly suppressed.[1] At all events, it speedily became excessively scarce; and we are not aware that it has ever been referred to by any subsequent writer on commerce.

The disordered state of the coin, and the proceedings relative to the great recoinage, in the reign of William III., led to a great deal of discussion both in and out of parliament, and contributed, in no ordinary degree, to diffuse juster notions respecting money and commerce. It was then that Mr Locke published his well-known tracts on Money.[2] They immediately obtained a very extensive circulation; and though infected with some very grave errors, had a powerful influence in preventing the success of Mr Lowndes's proposal for degrading the standard of the coin, and in contributing to establish the true theory of money. The restoration of the currency was not, however, effected without great opposition. A large minority in parliament supported Lowndes's views; and they were also supported by a number of writers. Of these, Mr Nicholas Barbon seems to have been one of the ablest. In his tract entitled A Discourse concerning Coining the New Money Lighter, published in 1696, he detected several of the errors into which Locke had fallen; and he had the further merit of ably demonstrating the fallacy of the popular opinions respecting the balance of trade; and of showing that no bullion could ever be sent abroad in payment of an unfavourable balance, unless it were at the time the cheapest and most profitable article of export.

Mr Barbon.

The inferences deduced by Barbon from his investigations into the balance of trade and foreign exchange are:

"That a trading nation is made rich by traffic and the industry of the inhabitants—and that the native stock of a nation can never be wasted.

"That no sort of commodities ought to be totally prohibited—and that the freer trade is, the better the nation will thrive.

"That the poverty and riches of a nation does not depend on a lesser or greater consumption of foreign trade, nor on the difference of the value of those goods that are consumed.

"That the balance of trade is a notion that serves rather to puzzle all debates of trade, than to discover any particular advantages a nation may get by regulating of trade.

"That the balance of trade (if there be one) is not the cause of sending away the money out of a nation: But that proceeds from the difference of the value of bullion in several countries, and from the profit that the merchant makes by sending it away more than by bills of exchange.

"That there is no occasion to send away money or bullion to pay bills of exchange, or balance accounts.

"That all sorts of goods, of the value of the bill of exchange, or the balance of the account, will answer the bill, and balance the account as well as money." (P. 59.)

It is singular, that a writer possessed of such sound and enlarged opinions respecting the principles of commercial intercourse, and who had shown that bullion differed in no respect from other commodities, should have maintained that the value of coined money depended on the stamp affixed to it by government. This gross and unaccountable error destroyed the effect of Barbon's tract; and was, most probably, the cause of the oblivion into which it very soon fell, and of its never having attracted that attention to which, on other accounts, it was justly entitled.

Dr Davenant.

The commercial writings of Dr Davenant, inspector-general of imports and exports, were published in the interval between 1695 and 1711. Though a partisan of the mercantile system, Dr Davenant had emancipated himself from many of the prejudices of its more indiscriminate and zealous supporters. He considered a watchful attention to the balance of trade, and its "right government," as of the highest importance; but he did not consider wealth as consisting exclusively of gold or silver; or that prohibitions and restrictions should be rashly imposed, even on the intercourse with those countries with which the balance was supposed to be unfavourable. But we are far from thinking that his commercial writings deserve the eulogies that rogress of Commer- al Science n England.

[2] Considerations on the Lowering of Interest and Raising the Value of Money, 1691. Further Considerations concerning Raising the Value of Money, 1695.

have been bestowed on them, or that they had any material effect in accelerating the progress of sound commercial science. They do not, in fact, contain a single principle not to be found in the work of Sir Josiah Child. Some of Dr Davenant's paragraphs are exceedingly good; but the treatises of which they form a part are remarkably inconclusive, and are for the most part pervaded by narrow and contracted views. There is no evidence to show that he was at all aware of the influence of commerce in facilitating the production of wealth, by giving rise to the territorial division of labour, and enabling each people to devote itself, in preference, to those employments for the successful prosecution of which they have some natural advantage.[1]

acob Van- erlint.

In 1734, Jacob Vanderlint, who describes himself as a tradesman, published his tract entitled Money answers all Things. Dugald Stewart has referred to it in the Appendix to his Life of Dr Smith, and has quoted some passages illustrative of the advantages of commercial freedom, which, he truly says, "will bear a comparison, both in point of good sense and of liberality, with what was so ably urged by Mr Hume twenty years afterwards, in his Essay on the Jealousy of Trade." Vanderlint closes his pamphlet with an argument in favour of the substitution of a territorial tax in place of every other; an idea borrowed from Locke, and subsequently adopted by the French economists.

ir Mat- hew ecker.

In 1744,[2] Sir Matthew Decker, an extensive merchant, published an Essay on the Causes of the Decline of Foreign Trade. This essay has been frequently referred to by Dr Smith, and it deserved his notice. Sir Matthew is a most intelligent and decided enemy of restrictions, monopolies, and prohibitions. To give full freedom to industry—he proposed that corporation privileges should be abolished; and that the existing taxes should be repealed, and replaced by a *single tax* laid on the consumers of luxuries, proportionally to their incomes. The following extracts will give an idea of the spirit and ability which pervades Sir Matthew's work:—

"In the Memoirs of De Witt, it is said, 'that restraint is always hurtful to trade;' the reason whereof is plain; for nature has given various products to various countries, and thereby knit mankind in an intercourse to supply each other's wants. To attempt to sell our products, but to buy little or none from foreigners, is attempting an impossibility, acting contrary to the intent of nature, cynically, and absurdly, and, as ours is a populous manufacturing country, might be prejudicial to our interests; for, could we raise all necessaries and vanities within ourselves, this intercourse designed by nature would be destroyed; and then, how is our navy, our only bulwark, to be maintained?" (P. 147.)

"Trade cannot, will not, be forced; let other nations prohibit, by what severity they please, interest will prevail; they may embarrass their own trade, but *cannot hurt a nation whose trade is free, so much as themselves.* Spain has prohibited our woollens; but had a reduction of our taxes brought them to their natural value only, they would be the cheapest in Europe of their goodness, consequently must be more demanded by the Spaniards, be smuggled into their country in spite of their government, and sold at better prices; their people would be dearer clothed, with duties and prohibitions, than without, consequently must sell their oil, wine, and other commodities dearer; whereby other nations, raising the like growths, would gain ground upon them, and their balance of trade grow less and less. But should we, for that reason, prohibit their commodities? By no means; for the dearer they grow, no more than what are just necessary will be used; their prohibition does their own business; some may be necessary for us; what are so, we should not make dearer to our own people; some may be proper to assort cargoes for other countries, and why should we prohibit our people that advantage? *Why hurt ourselves to hurt the Spaniards?* If we would retaliate effectually upon them for their ill intent, handsome premiums given to our plantations to raise the same growths as Spain might enable them to supply us cheaper than the Spaniards could do, and establish a trade they could never recover. Premiums may gain trade, but prohibitions will destroy it." (P. 163.)

Progress of Commercial Science in England.

Sir Matthew applies the same argument to expose the absurdity and injurious effect of the restraints on the trade with France. "I allow," he says, "that Britain should be always vigilant over the designs of France, but need not be afraid of her power; her wise regulations in trade should be the objects we should keep our eyes upon, and out-do her if possible; or else, as she rises, we must sink. But it is our comfort, that our remedy is always in our own hands; nor can there be any solid reason for the nation's paying dearer to other countries for goods we could buy cheaper in France. Would any wise dealer in London buy goods of a Dutch shopkeeper for 15d. or 18d. when he could have the same from a French shopkeeper for 1s.? Would he not consider, that, by so doing, he would empty his own pockets the sooner, and that, in the end, he would greatly injure his own family by such whims? And shall this nation commit an absurdity that stares every private man in the face?......The certain way to be secure is to be more powerful, that is, to extend our trade as far as it is capable of; and as restraints have proved its ruin, to reject them, and depend on freedom for our security; bidding defiance to the French, or any nation in Europe, that took umbrage at our exerting our natural advantages." (P. 184.)

We do not know that the impolicy of restrictions on the importation of foreign corn has ever been more ably and triumphantly exposed than in the following passage: "Every home commodity, in a free trade, will find its natural value; for, though that fluctuates, as of necessity it must, according to the plentifulness or scarcity of seasons, yet, for the home consumption, every home commodity must have great advantage over the foreign, as being upon the spot, and free from freight, insurance, commission, and charges, which on the produce of lands, being all bulky commodities, must in general be about 15 per cent., and a greater advantage cannot be given without prejudice; for 15 per cent. makes a great difference in the price of necessaries between the nation selling and the nation buying, and is a great difficulty on the latter, but, arising from the natural course of things, cannot be helped; though it is a sufficient security to the landholder, that foreigners can never import more necessaries than are absolutely required; and I presume, in such cases, they have more charity than to starve the people merely for an imaginary profit, which yet would prove their ruin in the end; for it is a fallacy and an absurdity to think to raise the value of lands by oppressions on the people that cramp their trade; for if trade declines, the common people must either come upon the parish, or fly for business to our neighbours: in the first case, they

---

[1] The progress of enlarged and liberal opinions with regard to commerce seems to have been in no small degree counteracted by the publication of the British Merchant. This work was written by some of the first merchants of their time, to expose the alleged defects in the commercial treaty with France, negotiated by Queen Anne's Tory administration in 1713. It consists of a series of papers published weekly, and afterwards collected in three volumes. Public opinion being very much against the treaty, the British Merchant enjoyed a large share of popularity. Its authors appear to have been thoroughly imbued with all the prejudices of the mercantile sect; and the work is now only deserving of notice as containing the fullest exposition of their peculiar doctrines.

[2] We quote from the edition of the Essay published at Edinburgh in 1756. It appears from the work itself (p. 4), that it had been written in 1740; the first edition was in 4to.

Progress of Commercial Science in England.

become a heavy tax on the rich, and, instead of buying the produce of their lands, must have it given them; and in the second case, when the consumers are gone, what price will the produce of land bear?" (P. 56.)

Mr Hume.

Mr Harris.

Of a work so well known as Mr Hume's Political Essays (published in 1752) it is almost superfluous to speak. The ability with which he has combated the prejudice against the French trade, and ridiculed the fear of being deprived of a sufficiency of bullion; the liberality and expansion of his views respecting commerce; and the beauty of his illustrations, cannot be too highly praised. It did not, however, enter into his plan to give a systematic view of the influence of commerce, nor has he instituted any analysis of the sources of wealth. Mr Harris endeavoured to supply the latter deficiency; and his Essay on Money and Coins, published in 1757, is, perhaps, on the whole, the best economical treatise that appeared previously to the publication of the Wealth of Nations. We have already noticed Harris's mistake of supposing that it was more profitable to import durable rather than rapidly consumable commodities; and, as a writer on commerce, he is undoubtedly very inferior to Sir Dudley North and Sir Matthew Decker. But the comprehensive and able manner in which he has treated the subject of money, the skill with which he has illustrated the effects of the division of labour in facilitating production and increasing wealth, and the near approach he has made to some of the fundamental doctrines of Dr Smith, if they do not give him a pre-eminence, certainly place him in the first rank among his precursors.

Early Italian writers on commerce.

We have been induced to treat of the progress of commercial science in England at considerable length, partly on account of the interest and importance of the subject, and partly because we are not acquainted with any work in which it has been investigated. Say and other continental writers contend that the Italians and French were the first who discovered and established the just principles of commercial intercourse. But the details now given prove the indisputable priority of the English. The economical works of Davanzati, Serra, Turbolo, and Scaruffi, are almost wholly occupied with a discussion of the effects of a forced reduction of the standard of money. They deserve credit for having opposed all tampering with the currency; but the arguments they employ to show its injustice and impolicy are stated with much greater brevity and force in Sir Robert Cotton's speech in the Privy Council in 1626. The *Discurso Economico* of Bandini, the earliest writer on commerce whose works have been thought worthy of a place in the voluminous collection of Italian works on Political Economy,[1] was published so late as 1737. Belloni and Algarotti's Essays on Commerce, both very inferior to the works of Sir Josiah Child or Sir Dudley North, were published, the former in 1750, and the latter in 1763.

Early French Writers o Commer

The French have still less claim than the Italians to be considered the discoverers of the true principles of commerce. There are many just and striking observations on the injury France sustained from the want of a free internal traffic, and the oppressiveness of taxation, in the *Dixme Royale* of Marshal Vauban, written in 1698. But Vincent de Gournay, whom the French state to be one of the earliest of their authors who entertained comprehensive and liberal notions regarding commerce, was born so late as 1712.[2] Gournay published translations of the treatise of Sir Josiah Child, and of a tract of Sir Thomas Culpepper, at Paris, in 1752. So slow was the progress of economical science in France, that even Montesquieu has a chapter entitled "*A quelles nations il est désavantageux de faire le commerce.*"[3]

System o the Frenc economists.

M. Quesnay.

But neither the efforts of the English nor French writers in favour of the freedom of commerce and industry had any considerable influence on the mercantile system. Their opinions respecting the nature of wealth, and the causes of national opulence, being confused and contradictory, their arguments in favour of a liberal system of commerce had somewhat of an empirical appearance, and failed of making that impression which is always made by arguments founded on well-established principles, and shown to be consistent with experience. Locke, as will be afterwards seen, entertained correct opinions respecting the paramount influence of labour in the production of wealth; but he did not prosecute his investigations in the view of elucidating the principles of this science, and made no reference to them in his subsequent writings. Harris adopted Locke's views, and deduced from them some practical inferences of great importance; but his general reasonings are merely introductory to his Treatise on Money, and are not illustrated with that fulness of detail, or in that comprehensive and systematic manner, necessary in scientific works. The celebrated M. Quesnay, a physician attached to the court of Louis XV., was the first who attempted to investigate and analyse the sources of wealth, with the intention of ascertaining the fundamental principles of political economy, and who, consequently, gave it a systematic form, and raised it to the rank of a science. Quesnay's father was a small proprietor, and having been educated in the country, he was naturally inclined to regard agriculture with more than ordinary partiality. At an early period of his life, being struck with its depressed state in France, he set himself to discover the causes which had prevented its making that progress which the industry of the inhabitants, the fertility of the soil, and the excellence of the climate, seemed to insure. In the course of this inquiry, he speedily discovered that the prohibition of exporting corn to foreign countries, and the preference given by the system of Colbert to the manufacturing and commercial classes over the agriculturists, had formed the most powerful obstacle to the progress and improvement of agriculture. But Quesnay did not satisfy himself with exposing the injustice of this preference, and its pernicious consequences. His zeal for the interests of agriculture led him, ystem of e French Economists.

---

[1] *Scrittori Classici Italiani di Economia Politica.* The publication of this collection of the works of her economical writers does honour to Italy, or rather to Napoleon, by whom it was liberally patronised. It was begun in 1803 and finished in 1805, in 50 volumes 8vo.

[2] See Dupont's edition *Des Œuvres de M. Turgot*, tom. iii. p. 311.

[3] Maupertuis, in his Eloge of Montesquieu, candidly admits that France is indebted for the science of commerce, finance, and population, to England. The passage is curious: "Comme le plan de Montesquieu," he observes, "renfermoit tout ce qui peut être utile au genre humain, il n'a pas oublié cette partie essentielle qui regarde le commerce, les finances, la population; science *si nouvelle parmi nous*, qu'elle n'y a encore point de nom. C'est *chez nos voisins qu'elle est née; et elle y demeura jusque à ce que M. Melon lui fit passer le mer.*"

Melon's work, *Essai Politique sur le Commerce*, was published in 1734. It is entirely founded on the principles of the mercantile system. Mr Bindon translated it into English, and published it, along with some rather valuable annotations and remarks, at Dublin, in 1739.

Melon had advocated the ruinous policy of raising the denomination of the coin. This gave occasion to the publication of an acute work by Dutot, entitled *Réflexions Politiques sur les Finances et le Commerce*, 2 tomes 12mo, 1738. Dutot's work was in its turn very ably criticised by Duverney, in his *Examen des Réflexions Politiques sur les Finances*, &c. 2 tomes 12mo, 1740. These works contain a great deal of curious and interesting information respecting French finance. Duverney's account of the *Mississippi Scheme* is particularly good.

not merely to place it on the same level with manufactures and commerce, but to raise it above them, by endeavouring to show that it was the only species of industry which really increased the riches of a nation. Founding on the fact, that everything which either ministers to our wants, or gratifies our desires, must be originally derived from the earth, Quesnay assumed as a self-evident truth, that the earth is the only source of wealth, and held that industry is altogether incapable of producing any new value, except when employed in agriculture, including therein fisheries and mines.[1] His observation of the striking effects of the vegetative powers of nature, and his inability to explain the real origin and causes of rent, confirmed him in his opinion. The fact, that of all who engage in laborious undertakings, none but the cultivators of the soil pay rent for the use of natural agents, appeared to him an incontrovertible proof that agriculture is the only species of industry which yields a nett surplus (*produit net*) over and above the expenses of production. Quesnay allowed that manufacturers and merchants are highly useful; but as they realize no nett surplus in the shape of rent, he contended they did not add any greater value to the raw material of the commodities they manufacture or carry from place to place, than the mere equivalent of the capital or stock consumed in these operations. These principles once established, it followed that landlords, farmers, and labourers employed in agriculture, were the only *productive* classes in a state; and that the labour of manufacturers and traders being *unproductive*, their means of subsistence and wealth were wholly derived from the agriculturists. It further followed, that the expenses of government, and the various public burdens, however imposed, must be defrayed out of the *produit net*, or rent of the landlords; and, consistently with this principle, Quesnay proposed that all the existing taxes should be repealed, and that a single tax (*l'impôt unique*), levied directly from the produce of the land, should be imposed in their stead.

The *economical table* of M. Quesnay—" Cette formule étonnante," says Dupont, " qui peint la naissance, la distribution, et la reproduction des richesses, et qui sert à calculer avec tant de sureté, de promptitude, et de précision, l'effet de toutes les opérations relatives aux richesses"—was published at Versailles in 1758.

But, however much impressed with the importance of agriculture over every other species of industry, Quesnay did not solicit for it any exclusive favour or protection. He successfully contended, that the interests of the agriculturists, as of all other classes, would be best promoted by establishing a system of perfect freedom. He showed that it could never be the interest of the proprietors and cultivators of the soil to fetter or discourage the industry of merchants, artificers, and manufacturers; for the greater the liberty they enjoyed, the greater would be their competition, and their products would, in consequence, be sold so much the cheaper. Neither, on the other hand, could it ever be the interest of the unproductive classes to harass and oppress the agriculturists, either by preventing the free exportation of their products, or by imposing on them any restrictive regulations. When the cultivators enjoy the greatest degree of freedom, their industry, and consequently their *surplus produce*—the only fund from which any accession of national wealth can be derived—will be carried to the greatest possible extent. According to this " liberal and generous system" (*Wealth of Nations*, p. 303[2]), the establishment of perfect liberty, perfect security, and perfect justice, is the only, as it is the infallible, means of securing the highest degree of prosperity to all classes of society.

System of the French Economists.

" On a vu," says the commentator of this system, M. Mercier de la Rivière, " qu'il est de l'essence de l'ordre que l'intérêt particulier d'un seul ne puisse jamais être séparée de l'intérêt commun de tous; nous en trouvons une preuve bien convaincante dans les effets que produit naturellement et nécessairement la plénitude de la liberté qui doit regner dans le commerce, pour ne point blesser la propriété. L'intérêt personnel, encouragée par cette grande liberté, presse vivement et perpétuellement chaque homme en particulier, de perfectionner, de multiplier les choses dont il est vendeur, de grossir ainsi la masse des jouissances qu'il peut procurer aux autres hommes, afin de grossir, par ce moyen, la masse des jouissances que les autres hommes peuvent lui procurer en échange. *Le monde* alors *va de lui-même;* le désir de jouir, et la liberté de jouir, ne cessant de provoquer la multiplication des productions et l'accroissement de l'industrie, ils impriment à toute la société un mouvement qui devient une tendance perpétuelle vers son meilleur état possible." (Tome ii. p. 444.)[3]

We shall have other opportunities of fully examining the principles of this theory. At present, it is sufficient to remark, that, in assuming agriculture to be the only source of wealth, because the matter of which commodities are composed is originally derived from the earth, Quesnay and his followers mistake altogether the nature of production, and really suppose wealth to consist of matter. But, in its natural state, matter is very rarely possessed of utility, and is

---

[1] " Cherchant d'où vient les richesses des nations. Quesnay trouva qu'elles ne naissent que des travaux dans lequels la *Nature et la Puissance Divine* concourent avec les efforts pour produire ou faire recueillir des productions nouvelles : de sorte qu'on ne peut attendre l'augmentation des ces richesses que de la cultivation, de la pêche, et de l'exploitation des mines, et des carriers." (See the *Notice sur les Economistes*, by one of the most zealous of the sect, *Dupont de Némours*, in the *Œuvres de Turgot*, tom. iii. p. 312.)

[2] M'Culloch's edition, 1 vol. 8vo.

[3] That Quesnay is entitled to the merit of originality cannot, we think, be disputed. He had certainly, however, been anticipated in several of his peculiar doctrines by some English writers of the previous century. The fundamental principles of the economical system are distinctly and clearly stated in a tract entitled Reasons for a Limited Exportation of Wool, published in 1677. " That it is of the greatest concern and interest of the nation," says the author of the tract, " to preserve the nobility, gentry, and those to whom the land of the country belongs, at least, much greater than a few artificers employed in working the superfluity of our wool, or the merchants who gain by the exportation of our manufactures, is manifest—1. Because they are the masters and proprietaries of the foundation of all the wealth in this nation, all profit arising out of the ground, which is theirs : 2. Because they bear all taxes and public burdens; which, in truth, are only borne by those who buy, and sell not; all sellers raising the price of their commodities, or abating of their goodness, according to their taxes." (Not being able to procure the pamphlet itself, we quote from the extract given in Mr Smith's Memoirs of Wool, vol. i. p. 254.)

In 1696, Mr Asgill published a treatise entitled Several Assertions Proved, in order to Create Another Species of Money than Gold, in support of Dr Chamberlayne's proposition for a Land Bank. We extract from this treatise the following passage, breathing, as Dugald Stewart has justly observed, the very spirit of Quesnay's philosophy.

" What we call commodities is nothing but land severed from the soil. Man deals in nothing but earth. The merchants are the factors of the world, to exchange one part of the earth for another. The king himself is fed by the labour of the ox; and the clothing of the army and the victualling of the navy must all be paid for to the owner of the soil, as the ultimate receiver. All things in the world are originally the produce of the ground, and there must all things be raised." (This passage has been quoted in Lord Lauderdale's Inquiry into the Nature and Origin of Public Wealth, 2d ed. p. 109.)

These passages are interesting, as exhibiting the first germs of the theory of the Economists. But there is no reason whatever to suppose that Quesnay was aware of the existence of either of the tracts referred to. The subjects treated in them were of too local a description to excite the attention of foreigners; and Quesnay was too candid to conceal his obligations, had he really owed always destitute of value. It is only by means of the labour bestowed in the appropriation of matter, and in fitting and preparing it for use, that it acquires exchangeable value, and becomes wealth. Human industry does not produce wealth by making any additions to the matter of our globe, this being a quantity susceptible neither of augmentation nor diminution. Its real effect is simply to produce wealth by giving utility to matter already in existence; and it will be hereafter seen, that the labour employed in manufactures and commerce is as productive of utility, and consequently of wealth, as that employed in agriculture. Neither is the cultivation of the soil, as Quesnay supposed, the only species of industry which yields a surplus over the expenses of production. When none but the best soils are cultivated, and when, consequently, agriculture is most productive, no rent, or *produit net*, is obtained from the land; and it is only after recourse has been had to poorer soils, and when the productive powers of the labour and capital employed in cultivation begin to diminish, that rent begins to appear; so that, instead of its being any proof of the superior productiveness of agricultural industry, rent is a consequence of its becoming less productive! The opinion of Quesnay, that man derives no assistance from the productive powers of nature, unless when employed in agriculture, is totally destitute of foundation; and, in a subsequent part of this article, it will be shown that the manufacturer and merchant derive fully as much assistance from these powers as the agriculturist, fisher, or miner.

Though the theory of the French economists, considered in reference to the fundamental principles of the science, was equally erroneous with that to which it was opposed, its novelty and ingenuity, its systematical and consentaneous form, the liberal system of commercial intercourse which it recommended, and the benevolent and excellent character of its founder, speedily obtained for it a very high degree of reputation. The opinions of Quesnay were early communicated to, and zealously espoused by, his friends the Marquis de Mirabeau, Mercier de la Rivière, Dupont de Némours, and others; and were afterwards advocated by Turgot, one of the most distinguished statesmen of whom France has to boast;[1] and by Letrosne, Condorcet, Raynal, and most of the succeeding French writers on commerce and finance. Their practical influence on the legislation of the country has also been considerable. In 1763 the free transportation of corn from one province to another was permitted; and in 1764 liberty was given to export it to foreign countries whenever the home price did not exceed thirty livres the septier (48s. the quarter). This last edict, after being suspended in 1770, was again revived in 1778 during the administration of Turgot. But the facility given to the imposition of the *contribution foncière* should certainly be considered as the greatest practical achievement of the economists; and there is but too much reason to fear it will long continue to afford a palpable demonstration of the fallacy of their doctrines.[2]

Notwithstanding the defects of their theory, the labours of the French economists contributed powerfully to accelerate the progress of economical science. In reasoning on subjects connected with national wealth, it was now found to be necessary to subject its sources, and the laws which regulate its production and distribution, to a more accurate and searching analysis. In the course of this examination, it was speedily ascertained that the mercantile and economical theories were alike erroneous and defective; and that to establish the science on a firm foundation, it was necessary to take a much more extensive survey, and to seek for its principles, not in a few partial and distorted facts, or in metaphysical abstractions, but in the connection subsisting among the various phenomena manifested in the progress of civilization. The Count di Verri, whose Meditations on Political Economy were published in 1771, pointed out the fallacy of the opinions entertained by the French economists respecting the superior productiveness of agriculture; and showed that all the operations of industry really consist of modifications of matter already in existence.[3] But Verri did not trace the consequences of this important principle; and, possessing no clear and definite notions of what constituted wealth, he did not attempt to discover the means by which labour might be facilitated. He made several valuable additions to particular branches of the science, and had sufficient acuteness to detect the errors in the systems of others; but the task of constructing a better system in their stead required talents of a far higher order.

Wealth of Nations.

At length, in 1776, our illustrious countryman, Adam Smith, published the Wealth of Nations—a work which has done for political economy what the *Principia* of Newton did for physics, and the *Esprit des Loix* of Montesquieu for politics. In this work the science was, for the first time, treated in its fullest extent, and many of its fundamental

---

them any. It is probable he may have seen Locke's treatise on Raising the Value of Money, where the idea is thrown out that all taxes fall ultimately on the land. But there is an immeasurable difference between the suggestion of Locke and the well-digested system of Quesnay.

[1] Turgot's *Réflexions sur la Formation et la Distribution des Richesses*, published in 1771, is certainly the best of all the works founded on the principles of the Economists, and is, in some respects, the best work on Political Economy published previously to the Wealth of Nations.

[2] Exclusive of the *Réflexions* of Turgot, the following are the principal works published by the French Economists:—

Tableau Economique, et Maximes Générales du Gouvernement Economique, par François Quesnay, 4to. Versailles, 1758.
Théorie de l'Impôt, par M. de Mirabeau, 4to, 1760.
L'Ami des Hommes, par M. de Mirabeau, seven tomes, 1760, &c.
Eléments de la Philosophie Rurale, par M. de Mirabeau, three tomes 12mo, 1763.
L'Ordre Naturel et Essentiel des Sociétés Politiques, par Mercier de la Rivière, 4to, and two tomes 12mo, 1767.
Sur l'Origine et Progrès d'une Nouvelle Science, par Dupont de Némours, 1767.
La Physiocratie, ou Constitution Naturelle du Gouvernement le plus avantageux aux genre humain, par Quesnay, two tomes, 1767.
Lettres d'un Citoyen à un Magistrat, sur les Vingtièmes et les autres Impôts, par l'Abbé Baudeau, 1768.

[3] "Alcuni benemeriti scrittori, rattristati dai gravi disordini, che soffrono i popoli per le gabelle, sono passati all'estremo de considerare ingiusto e mal collocato il tributo se non ripartito sui fondi di terra, e colla creazione di un linguaggio ascetico, hanno eretta la setta degli economisti, presso la quale ogni uomo che non adoperi l'aratro, e un essere sterile, e i manifattori si chiamano una *classe sterile.* Rispettando il molto di vero e di utile che da essi è stato scritto, io non saprei associarmi alla loro opinione ne sul tributo, ne su di questa pretesa classe sterile. La riproduzione e attribuibile alla manifattura ugualmente, quanto al laroro de campi. Tutti i fenomini dell' universo, sieno essi prodotti dalla mano dell'uomo o vero dalle universali leggi della fisica, non ci danno idea di attuale *creazione*, ma unicamente di una *modificazione* della materia. *Accostare e seperare* sono gli unici elementi che l'ingegno umano ritrova analizando l'idea della *riproduzione*; e tanto e riproduzione *di valore e di richezza* se la terra, l'aria, e l'aqua ne'campi si trasmutino in grano, come se colla mano dello uomo il glutine di un insetto si trasmuti in velluto, o vero alcuni pezzetti di metallo si organizzino a formare una ripetizione. Degli intieri citta, e degli stati intieri campano non d'altro che sul prodotto di questa fecondissima *classe sterile*, la di cui riproduzione comprende il valore della materia prima, la consumazione proporzionata delle mani impiegatevi, e di piu quella porzione che fa arrichire chi ha intrapresa la fabbrica e chi vi s'impiega con felice talento." (*Meditazioni sulla Economia Politica*, § 3.)

Wealth of Nations.

principles placed beyond the reach of cavil and dispute. In opposition to the French economists, Dr Smith showed that *labour* is the only source of wealth, and that the desire inherent in the breast of every individual to improve his fortune and rise in the world is the cause of its accumulation. He next traced the means by which the powers of labour may be rendered most effective, and showed that it is productive of wealth when employed in manufactures and commerce, as well as in the cultivation of the land. Having established these principles, Smith showed, in opposition to the commonly received opinions of the merchants and statesmen of his time, that wealth did not consist in the abundance of gold and silver, but in that of the various necessaries, conveniencies, and enjoyments of human life; he showed that individuals are always the best judges of what is for their own interest, and that in prosecuting branches of industry advantageous to themselves, they necessarily prosecute such as are advantageous to the public.[1] Thence Dr Smith drew his grand inference, that every regulation intended to force industry into particular channels, or to determine the commercial intercourse to be carried on between different parts of the same country, or between distant and independent countries, is impolitic and pernicious —injurious to the rights of individuals, and adverse to the progress of real opulence and lasting prosperity.

The fact that traces of most of these principles, and that the distinct statement of some of the more important, may be found in the works of previous writers, detracts but little from the merits of Dr Smith. In adopting the discoveries of others, he made them his own; he demonstrated the truth of principles on which his predecessors had, in most cases, stumbled by chance; separated them from the errors by which they were encumbered; traced their remote consequences; pointed out their limitations; showed their practical importance and real value,—their mutual dependence and relation; and reduced them into a consistent and well-compacted system. We do not mean to say that Smith produced a perfect work. Undoubtedly there are errors, and those, too, of no slight importance, in the Wealth of Nations. The principles to which we have just referred, and which form the basis of the work, are unimpeachable. Smith, however, has not always reasoned correctly from them, and he has occasionally introduced others, which a more careful observation and analysis has shown to be ill founded. But, after every allowance has been made for these defects, enough still remains to justify us in considering him as the real founder of the science. If he has not left a perfect work, he has at all events left one which contains a greater mass of useful and universally interesting truths than have ever been given to the world by any other individual; and he has pointed out and smoothed the route, by following which, subsequent philosophers have been enabled to perfect much that he had left incomplete, to rectify the mistakes into which he fell, and to make many new and important discoveries. Whether, indeed, we refer to the soundness of its leading doctrines, to the liberality and universal applicability of its practical conclusions, or to the powerful and beneficial influence it has had on the improvement and progress of economical science, and on the policy and destiny of nations, Smith's work must be placed in the foremost rank of those that have done most to liberalise, enlighten, and enrich mankind.

Distinction between Politics and Political Economy.

The practical part of the science of political economy was long confounded with that of politics; and it is undoubtedly true that they are very intimately connected, and that it is frequently impossible to treat those questions which strictly belong to the one without referring more or less to the principles and conclusions of the other. But, in their leading features, they are sufficiently distinct. The laws which regulate the production and distribution of wealth are the same in every country and stage of society. Those circumstances which are favourable or unfavourable to the increase of riches and population in a republic may equally exist, and will have exactly the same effects, in a monarchy. That security of property, without which there can be no steady and continued exertion,—that freedom of engaging in every different branch of industry, so necessary to call the various powers and resources of human talent and ingenuity into action,—and that economy in the public expenditure, so conducive to the accumulation of national wealth,—are not the exclusive attributes of any particular species of government. If free states have generally made the most rapid advances in wealth and population, it is an indirect rather than a direct consequence of their political constitution. It results more from the greater security which a popular government presents, that the right of property will be held sacred,—that the freedom of industry will be less fettered and restricted,—and that the public income will be more judiciously levied and expended, than from the circumstance of a greater proportion of the people being permitted to exercise political rights and privileges. Give the same securities to the subjects of an absolute monarch, and they will make the same advances. Industry does not require to be stimulated by extrinsic advantages. The additional comforts and enjoyments which it procures have always been found sufficient to insure the most persevering and successful exertions. And whatever may be the form of government, those countries always advance in the career of improvement, in which the public burdens are moderate, industry free, and every individual permitted peaceably to enjoy the fruits of his labour. It is not, therefore, so much on its political organization, as on the talents and spirit of its rulers, that the wealth of a country is principally dependent. Economy, intelligence, and liberality on the part of those in power, have frequently elevated absolute monarchies to a very high degree of opulence and prosperity; while all the advantages derived from a more liberal system of government have not been able to preserve free states from being impoverished and exhausted by the extravagance, intolerance, and short-sighted policy of their rulers.

Politics and political economy are, therefore, sufficiently distinct. The politician examines the principles on which government is founded, he endeavours to determine in whose hands the supreme authority may be most advantageously placed, and unfolds the reciprocal duties and obligations of the governing and governed portions of society. The political economist does not take so high a flight. It is not of the constitution of the government, but of its ACTS only, that he presumes to judge. Whatever measures affect the production or distribution of wealth, necessarily come within the scope of his observation, and are canvassed by him. He examines whether they are in unison with the principles of economical science. If they are, he pronounces them to be advantageous, and shows the nature and extent

---

[1] It is of importance to observe, that Dr Smith does not say that, in prosecuting such branches of industry as are most advantageous to themselves, individuals necessarily prosecute such as are at the same time *most* advantageous to the public. His leaning to the system of the Economists—a leaning perceptible in every part of his work—made him so far swerve from the principles of his own system, as to admit, that individual advantage is not always a true test of the public advantageousness of different employments. He considered that agriculture, though not the only productive employment, is the most productive of any; that the home trade is more productive than a direct foreign trade; and the latter than the carrying trade. It will be hereafter seen that there is no foundation for these distinctions.

Distinction between Politics and Political Economy.

of the benefits of which they will be productive; if they are not, he shows in what respect they are defective, and to what extent their operation will be injurious. But he does this without inquiring into the constitution of the government by which these measures have been adopted. The circumstance of their having emanated from the privy council of an arbitrary monarch, or the representative assembly of a free state, though in other respects of supreme importance, cannot affect the immutable principles by which he is to form his opinion upon them.

Distinction between statistics and political economy.

Besides being confounded with politics, the practical part of political economy has frequently been confounded with statistics; but they are still more easily separated and distinguished. The object of the statistician is to describe the condition of a particular country at a particular period; while the object of the political economist is to discover the causes which have brought it into that condition, and the means by which its wealth and riches may be indefinitely increased. He is to the statistician what the physical astronomer is to the mere observer. He takes the facts furnished by the statistician, and after comparing them with those furnished by historians and travellers, he applies himself to discover their relation. By a patient induction,—by carefully observing the circumstances attending the operation of particular principles,—he discovers the effects of which they are really productive, and how far they are liable to be modified by the operation of other principles. It is thus that the relation between rent and profit,—between profit and wages, and the various general laws which regulate and connect the apparently conflicting, but really harmonious interests of every different order of society, have been discovered and established with all the certainty of demonstrative evidence.

PART II.

PRODUCTION OF WEALTH.

SECT. I.—*Definition of Production.—Labour the only Source of Wealth.*

Definition of production.

All the operations of nature and of art are reducible to, and really consist of, transmutations,—of changes of form and of place. By production in this science, we are not to understand the production of matter, for that is exclusively the attribute of Omnipotence, but the production of utility, and consequently of exchangeable value, by appropriating and modifying matter already in existence, so as to make it satisfy our wants, and contribute to our enjoyments. The labour which is thus employed is the only source of wealth.[1] Nature spontaneously furnishes the matter of which commodities are made; but, independently of labour, matter is rarely of any use, and is never of any value. Place us on the banks of a river, or in an orchard, and we shall infallibly perish of thirst or hunger, unless, by an effort of industry, we raise the water to our lips, or pluck the fruit from its parent tree. It is seldom, however, that the mere appropriation of matter is sufficient. In the infinite majority of cases, labour is required not only to appropriate it, but to convey it from place to place, and to give it that peculiar shape, without which it may be totally useless, and incapable of either ministering to our necessities or our comforts. The coal used in our fires is buried deep in the bowels of the earth, and is absolutely worthless until the miner has extracted it from the mine, and brought it into a situation where it may be used. The stones and mortar of which our houses are built, and the rugged and shapeless materials from which the various articles of convenience and ornament with which they are furnished have been prepared, were, in their original state, alike destitute of value and utility. And of the innumerable variety of animal, vegetable, and mineral products which form the materials of our food and clothes, none were originally serviceable, while many were extremely noxious to man. His *labour* has given them utility, has subdued their bad qualities, and made them satisfy his wants, and minister to his comforts and enjoyments. "Labour was the first price, the original purchase-money, that was paid for all things. It was not by gold or by silver, but by labour, that all the wealth of the world was originally purchased." (*Wealth of Nations*, p. 14.)

Labour th only Sour of Wealt

Those who observe the progress and trace the history of the human race in different countries and states of society, will find their comfort and happiness always pretty nearly proportioned to their expertness in appropriating the raw products of nature, and in fitting and adapting them to their use. The savage, whose labour is confined to the gathering of wild fruits, or to the picking up of the shell-fish on the sea coast, is placed at the very bottom of the scale of civilization, and is, in point of comfort, decidedly inferior to many of the lower animals. The *first* step in the progress of society is made when man learns to hunt wild animals, to feed himself with their flesh, and clothe himself with their skins. But labour, when confined to the chase, is extremely barren and unproductive. Tribes of hunters, like beasts of prey, whom they closely resemble in their habits and modes of subsistence, are but thinly scattered over the surface of the countries which they occupy; and, notwithstanding the fewness of their numbers, any unusual deficiency in the supply of game never fails to reduce them to the extremity of want. The *second* step in the progress of society is made when the tribes of hunters and fishers apply their labour, like the ancient Scythians and modern Tartars, to the domestication of wild animals and the rearing of flocks. Their subsistence is much less precarious than that of hunters; but they are almost entirely destitute of the comforts and elegancies which give to civilized life its chief value. The *third* and most decisive step in the progress of civilization —in the great art of producing the necessaries and conveniencies of life—is made when the wandering tribes of hunters and shepherds renounce their migratory habits, and become agriculturists and manufacturers. It is then, properly speaking, that man begins fully to avail himself of his productive powers. He then becomes laborious, and, by a necessary consequence, his wants are then, for the first time, fully supplied, and he acquires an extensive command over the articles necessary to his comfort as well as his subsistence.

The earth not a sourc of wealth.

However paradoxical the assertion may at first sight appear, it is notwithstanding true that the earth does not gratuitously supply a single atom of wealth. It is a powerful machine given by Providence to man; but without his abour the ly Source Wealth.

---

[1] This point has been well stated by M. Destutt Tracy. "Non seulement," says he, "nous ne créons jamais rien, mais il nous est même impossible de concevoir ce que c'est que créer ou anéantir, si nous entendons rigoureusement par ces mots, faire quelque chose de rien, ou reduire quelque chose à rien; car nous n'avons jamais vu un être quelconque sortir du néant ni y rentrer. De là cet axiome admis par toute l'antiquité: rien ne vient de rien, et ne peut rédévenir rien. Que faisons-nous donc par notre travail, par notre action sur tous les êtres qui nous entourent? Jamais rien qu'opérer dans ces êtres des changements de forme ou de lieu qui les approprient à notre usage, qui les rendent utiles à la satisfaction de nos besoins. Voilà ce que nous devons entendre par produire; c'est donner aux choses une utilité qu'elles n'avoient pas. Quel que soit notre travail, s'il n'en resulte point d'utilité, il est infructeux; s'il en resulte, il est productif." (*Elémens d'Idéologie*, tome iii. p. 162.)

labour it would be altogether useless, and would for ever stand idle and unemployed. It is through the intervention of labour that the products of the earth become valuable and useful. Its surface is, in its natural state, covered with fruits and game; its bowels contain an infinite variety of mineral products; its seas and rivers are stored with fish; and it is endowed with inexhaustible vegetative and productive powers; but all these powers and products are plainly of no use, and have no value, until the labour of man renders the former subservient to his purpose, and appropriates the latter, and gives them the peculiar form required to fit them to support his existence and increase his enjoyments.

pinion of obbes.

The importance of labour in the production of wealth was very clearly perceived both by Hobbes and Locke. At the commencement of the 24th chapter (entitled Of the Nutrition and Procreation of a Commonwealth) of the Leviathan, published in 1651, Hobbes says, "The nutrition of a commonwealth consisteth in the plenty and distribution of materials conducing to life.

"As for the plenty of matter, it is a thing limited by nature to those commodities which, from (the two breasts of our common mother) land and sea, God usually either freely giveth, or for labour selleth to mankind.

"For the matter of this nutriment, consisting in animals, vegetables, minerals, God hath freely laid them before us, in or near to the face of the earth; so as there needeth no more but the labour and industry of receiving them: insomuch that plenty dependeth (next to God's favour) on the labour and industry of man."

pinion of ocke.

But Locke had a much clearer apprehension of this doctrine. In his Essay on Civil Government, published in 1689, he has entered into a lengthened and able analysis to show that the products of the earth owe almost all their value to labour. "Let any one consider," says he, "what the difference is between an acre of land planted with tobacco or sugar, sown with wheat or barley, and an acre of the same land lying in common, without any husbandry upon it, and he will find that the improvement of labour makes the far greater part of the value. I think it will be but a very modest computation to say, that of the products of the earth useful to the life of man, *nine tenths* are the effects of labour; nay, if we will rightly consider things as they come to our use, and cast up the several expenses about them, what in them is purely owing to nature, and what to labour, we shall find, that in most of them *ninety-nine hundredths* are wholly to be put on the account of labour.

"There cannot be a clearer demonstration of anything, than several nations of the Americans are of this, who are rich in land, and poor in all the comforts of life; whom nature having furnished as liberally as any other people with the materials of plenty, *i. e.* a fruitful soil apt to produce in abundance what might serve for food, raiment, and delight, yet, for want of improving it by labour, have not one hundredth part of the conveniencies we enjoy; and the king of a large and fruitful territory there feeds, lodges, and is worse clad than a day-labourer in England.

"To make this a little clear, let us but trace some of the ordinary provisions of life through their several progresses, before they come to our use, and see how much of their value they receive from human industry. Bread, wine, and cloth, are things of daily use, and great plenty; yet, notwithstanding, acorns, water, and leaves or skins, must be our bread, drink, and clothing, did not labour furnish us with these more useful commodities; for whatever bread is more worth than acorns, wine than water, and cloth or silk than leaves, skins, or moss, that is solely owing to labour and industry; the one of these being the food and raiment which unassisted nature furnishes us with; the other, provisions which our industry and pains prepare for us; which how much they exceed the other in value, when any one hath computed, he will then see how much labour makes the far greatest part of the value of things we enjoy in this world; and the ground which produces the materials is scarce to be reckoned on as any, or, at most, but a very small part of it.

Labour the only Source of Wealth.

"An acre of land that bears here twenty bushels of wheat, and another in America which, with the same husbandry, would do the like, are, without doubt, of the same natural intrinsic value. But yet the benefit mankind receives from the one in a year is worth L.5, and from the other possibly not worth *one penny;* if all the profit an Indian received from it were to be valued and sold here, at least, I may truly say, not $\frac{1}{1000}$. 'Tis labour, then, which puts the greatest part of value upon land, *without which it would scarcely be worth anything:* 'tis to that we owe the greatest part of its useful products; for all that the straw, bran, bread, of that acre of wheat, is more worth than the product of an acre of good land, which lies waste, is all the effect of labour. For 'tis not merely the ploughman's pains, the reaper's and thrasher's toil, and the baker's sweat, is to be counted into the bread we eat; the labour of those who broke the oxen, who digged and wrought the iron and stones, who felled and framed the timber employed about the plough, mill, oven, or any other utensils, which are a vast number, requisite to this corn, from its being seed to be sown, to its being made bread, must all be charged on the account of *labour*, and received as an effect of that; Nature and the earth furnishing only the almost worthless materials as in themselves. 'Twould be a strange catalogue of things that industry provided and made use of about every loaf of bread, before it came to our use, if we could trace them: Iron, wood, leather, barks, timber, stone, brick, coals, lime, cloth, dyeing drugs, pitch, tar, masts, ropes, and all the materials made use of in the ship that brought away the commodities made use of by any of the workmen, to any part of the work; all which, it would be almost impossible, at least too long, to reckon up." (*Of Civil Government*, book ii. § 40, 41, 42, and 43.)[1]

Had Locke carried his analysis a little further, he could not have failed to perceive that neither water, leaves, skins, nor any of the spontaneous products of nature, have any value except what they owe to the labour required to appropriate them. The value of water to a man placed on the bank of a river depends on the labour necessary to raise it to his lips; and its value, when carried ten or twenty miles off, is equally dependent on the labour necessary to convey it there. All the rude products, productive powers, and capacities of nature, are gratuitously offered to man. Nature is not niggardly or parsimonious. She neither demands nor receives an equivalent for her favours. An object which it does not require any portion of labour to appropriate or to adapt to our use, may be of the very highest utility; but, as it is the free gift of nature, it is impossible it can have the smallest value.[2]

---

[1] This is a very remarkable passage. It contains a far more distinct and comprehensive statement of the fundamental doctrine, that labour is the constituent principle of value, than is to be found in any other writer previous to Smith, or than is to be found even in the Wealth of Nations. But Locke does not seem to have been sufficiently aware of the value of the principle he had elucidated, and has not deduced from it any important practical conclusion. On the contrary, in his tract on the Raising of the Value of Money, published in 1691, he lays it down broadly that all taxes, however imposed, ultimately *fall on the land;* whereas it is plain he should, consistently with the above principle, have shown that they would fall, not exclusively on the produce of land, but generally on the produce of industry, or on all species of commodities.

[2] Bishop Berkeley entertained very just opinions respecting the source of wealth. In his Querist, published in 1735, he asks,—

Labour the only Source of Wealth.

"Si je retranche," to use a striking illustration of this doctrine given by M. Canard, "de ma montre, par la pensée, tous les travaux qui lui ont été successivement appliquées, il ne resterai que quelques grains de minéral placées dans l'intérieur de la terre, d'où on les a tirés, et où ils n'ont aucune valeur. De même, si je décompose le pain que je mange, et que j'en retranche successivement tous les travaux successifs qu'il a reçus, il ne restera que quelques tiges d'herbes, graminées, éparses dans des désertes inculcates, et sans aucune valeur." (*Principes d'Economie Politique*, p. 6.)

It is to labour, therefore, that man owes everything possessed of exchangeable value. Labour is the talisman that has raised him from the condition of the savage—that has changed the desert and the forest into cultivated fields—that has covered the earth with cities and the ocean with ships—that has given us plenty, comfort, and elegance, instead of want, misery, and barbarism.

Having established this fundamental principle—having shown that labour alone gives value to commodities—it is plain that the great practical problem of this science must resolve itself into a discussion of the means by which labour may be rendered most efficient, that is, by which the greatest amount of necessary and desirable products may be obtained with the least outlay of labour. Wealth, as already seen, is always increased by every diminution of the labour required to produce the articles of which it consists. Every measure and invention that has any tendency to save labour, or to reduce the cost of producing commodities, adds proportionally to our power of obtaining wealth and riches; while every measure or regulation that has any tendency to waste labour, or to raise the cost of producing commodities, equally lessens this power. This is the simple and decisive test by which we are to judge of every measure affecting the wealth of the country, and of every invention. If they render labour more productive—if they tend to reduce the value of commodities, to render them more easily obtainable, and, consequently, to bring them within the command of a greater portion of society—they are advantageous; but if their tendency be different, they are as certainly disadvantageous. Considered in this point of view, that great branch of the science which treats of the production of wealth will be found to be abundantly simple, and easily understood.

Labour, according as it is applied to the raising of raw produce—to the fashioning of that raw produce, when raised, into articles of utility, convenience, or ornament—and to the conveyance of raw and wrought products from one country and place to another—is said to be agricultural, manufacturing, and commercial. An acquaintance with the particular processes, and most advantageous methods, of applying labour in each of these great departments of industry, forms the appropriate study of the agriculturist, manufacturer, and merchant. It is not consistent with his objects for the political economist to enter into the details of particular businesses and professions. He confines himself to an investigation of the means by which labour generally may be rendered most productive, and how its powers may be increased in *all* departments of industry.

SECT. II.—*Means by which the Productive Powers of Labour are increased.—Security of Property.—Division of Labour.—Accumulation and Employment of Capital.*

Means by which the Product Powers of Labour may be increased.

The most careless and inattentive observer of the progress of mankind from poverty to affluence must have early perceived, that there are *three* circumstances whose conjoint operation is necessary to stimulate and improve the productive powers of industry. The *first*, and most indispensable, is the *security of property*, or a strong conviction in the mind of every individual that he will be allowed to dispose at pleasure of the fruits of his labour. The *second* is the introduction of exchange or barter, and the consequent appropriation of particular individuals to particular employments. And the *third* is the accumulation and employment of the produce of previous labour, or, as it is more commonly termed, of capital, or stock. Every improvement that either has been or that may yet be made, in the great art of producing the necessaries, comforts, and conveniencies of human life, will be found to be resolvable into the more judicious and successful application of one or more of those means of stimulating labour, and adding to its power. To give a full exposition of the nature and influence of each would far exceed the limits of this article; and we must content ourselves with such observations as may suffice to give a general idea of their operation.

Security of property.

SECURITY OF PROPERTY is the first and most indispensable requisite to the production of wealth. Its utility in this respect is so obvious and striking, as to make it be more or less respected in every country, and in the earliest and rudest periods of society. All have been impressed with the reasonableness of the maxim which teaches that those who sow should be permitted to reap; that the labour of a man's body and the work of his hands should be considered as exclusively his own. No horde, how barbarous soever, has been discovered in which the principle of *meum* and *tuum* was not recognised. Nothing, it is plain, could ever tempt any one to engage in any laborious employment—he would neither domesticate wild animals, nor clear and cultivate the ground, if, after months and years of toil, when his flocks had become numerous, and his harvests were ripening for the sickle, a stranger were allowed to rob him of the produce of his industry. No wonder, therefore, that the utility of some general regulations, securing to every individual the peaceable enjoyment of the produce he had raised, and of the ground he had cultivated and improved, suggested itself to the first legislators. The author of the book of Job places those who removed their neighbours' landmarks at the head of his list of wicked men; and some of the earliest profane legislators subjected those guilty of this offence to a capital punishment. (Goguet, *De l'Origine des Loix*, &c. tom. i. p. 30, 4to ed.)

Dr Paley has said that the law of the land is the real foundation of the right of property. But the obvious utility of securing to each individual the property acquired by his industry, has undoubtedly formed the irresistible reason which has induced every people emerging from barbarism to establish this right. It is, in truth, the foundation on which all the institutions of society rest. Until property

---

"Whether it were not wrong to suppose *land* itself to be wealth? And whether the *industry of the people* is not first to be considered as that which constitutes wealth, which makes even land and silver to be wealth, neither of which would have any value but as means and motives to industry?" "Whether, in the wastes of America, a man might not possess twenty miles square of land, and yet want his dinner, or a coat to his back." (*Querist*, Numbers 38 and 39.)

We shall afterwards notice Sir William Petty's opinion on this subject.

Say appears to think (*Discours Préliminaire*, p. 37), that Galiani was the first to show, in his treatise *Della Moneta*, published in 1750, that labour is the only source of wealth. But the passages we have now laid before the reader prove the erroneousness of this opinion. Galiani has entered into no analysis or argument to prove the correctness of his statement; and as it appears from other parts of his work that he was well acquainted with Locke's Tracts on Money, a suspicion naturally arises that he had seen the Essay on Civil Government, and that he was really indebted to it for a knowledge of this principle. This suspicion derives strength from the circumstance of Galiani being still less aware than Mr Locke of the value of the discovery. See *Trattato della Moneta*, p. 39, ediz. 1780.

urity of operty.

has been publicly guaranteed, men look on each other as enemies rather than as friends. The idle and improvident are always desirous of seizing on the earnings of the laborious and frugal; and were they not restrained by the strong arm of the law from prosecuting their attacks, they would, by generating a feeling of insecurity, effectually check both industry and accumulation, and sink all classes to the same level of hopeless misery as themselves. The security of property is quite as necessary to accumulation as to production. No man ever denies himself an immediate gratification when it is within his power, unless he think that by doing so he has a fair prospect of obtaining, at some future period, a greater accession of comforts and enjoyments, or of avoiding some considerable evil. Where the right of property is vigilantly protected, an industrious man, who produces as much by one day's labour as is sufficient to maintain him two days, instead of idling away the second day, accumulates the surplus which exceeds his wants as a capital; the increased consequence and enjoyments which the possession of capital brings along with it being, in the great majority of cases, more than sufficient to countervail the desire of immediate gratification. But wherever property is insecure, we look in vain for the operation of this principle. "It is plainly better for us," is then the invariable language of the people, "to enjoy while it is in our power, than to accumulate property we shall not be permitted to use, and which will either expose us to the extortion of a rapacious government, or to the depredations of those who exist only by the plunder of their more industrious neighbours."

The security of property is not violated merely when a man is deprived of the power of peaceably enjoying the fruits of his industry; it is also violated, and perhaps in a still more unjustifiable manner, when he is prevented from using his powers, in any way not injurious to others, that he considers most beneficial for himself. Of all the species of property a man can possess, the faculties of his mind and the powers of his body are most particularly his own. He should, therefore, be permitted to enjoy, that is, to use or exert these powers at discretion. And hence the right of property is as much, or more, infringed upon, when a man is interdicted from engaging in a particular branch of business, as it is when the property he has produced and accumulated is forcibly taken from him. Every monopoly which gives to a few individuals the exclusive power of carrying on certain branches of industry, is thus, in fact, established in direct violation of the right of property of every one else. It prevents them from using their natural capacities or powers in the way they might have considered best; and as every man who is not a slave is justly held to be the best, and, indeed, only judge of what is advantageous for himself, the principles of natural law and the right of property are both subverted when he is excluded from any employment. In like manner, the right of property is violated whenever any regulation is made to force an individual to employ his labour or capital in a particular way. The property of a landlord is violated when he is compelled to adopt any system of cultivation, even supposing it to be preferable to that which he would otherwise follow. The property of the capitalist is violated when he is obliged to accept a particular rate of interest for his stock; and the property of the labourer is violated whenever he is obliged to employ himself in any particular occupation.

ects of curity.

The finest soil, the finest climate, and the finest intellectual powers, can prevent no people from becoming barbarous, poor, and miserable, if they have the misfortune to be subjected to a government which does not respect the right of property. This is the greatest of all calamities. The ravages of civil war, of pestilence, and of famine, may be repaired; but nothing can enable a nation to contend against the deadly influence of an established system of violence and rapine. The want of security, of a lively and well-founded expectation of being permitted freely to dispose of the fruits of industry, is the principal cause of the wretched state of the Ottoman dominions in the present day, as it was of the decline of industry and arts in Europe during the middle ages. When the Turkish conquerors overran those fertile and beautiful countries in which, to the disgrace of the other European powers, they are still permitted to encamp, they parcelled them among their followers, on condition of their performing certain military services, on a plan corresponding, in many important particulars, to the feudal system of our ancestors. But these possessions are not hereditary. They do not descend to the children or legatees of the present possessors, but on their death revert to the sultan. Among the occupiers of land in Turkey there is, therefore, no thought of futurity. No one feels any interest about the prosperity of an unknown successor, and no one ever executes any improvement unless he expect to reap all the advantage during his own life. This is the cause why the Turks are so extremely careless about their houses. They never construct them of solid or durable materials. And it would be a gratification were they assured that they would fall to pieces the moment they have breathed their last. Under this miserable government the palaces have been changed into cottages, and the cities into villages. The long-continued want of security has extinguished the very spirit of industry, and destroyed not only the power, but even the desire, to emerge from barbarism.

Security of Property.

Had it been possible for arbitrary power to profit by the lessons of experience, it would long since have perceived that its own wealth, as well as that of its subjects, would be most effectually promoted by maintaining the inviolability of property. Were the Turkish government to establish a vigilant system of police, to give to each individual full power to dispose of the fruits of his labour, and to substitute a regular plan of taxation for the present odious system of extortion and tyranny, industry would revive, capital and population would be augmented, and moderate duties, imposed on a few articles in general demand, would bring a much larger sum into the coffers of the treasury than all that is now obtained by force and violence. The stated public burdens to which the Turks are subject, are light when compared with those imposed on the English, the Hollanders, or the French. But when the latter have paid the taxes due to government, they know they will be permitted peaceably to enjoy or accumulate the remainder of their earnings; whereas the Turk has no security but that the moment after he has paid his stated contribution, the pasha, or one of his satellites, may strip him of every additional farthing he possesses. Security is the foundation, the principal element, in every well-digested system of finance. When maintained inviolate, it enables a country to support, without much difficulty, a very heavy load of taxes; but where there is no security, where property is a prey to rapine and spoliation, to the attacks of the needy, the powerful, or the profligate, the smallest burdens are justly regarded as oppressive, and uniformly exceed the means of the impoverished and spiritless inhabitant.

Case of the Jews.

The Jews have been supposed to afford an instance of a people whose property has been long exposed to an almost uninterrupted series of attacks, and who have, notwithstanding, continued to be rich and industrious. But when rightly examined, it will be found that the case of the Jews forms no exception to the general rule. The absurd prejudices with which the Jews have been almost universally regarded, prevented their acquiring any property in land, and excluded them from participating in the charitable institutions of the different countries among which they are scattered. Having therefore no adventitious sup-

Security of Property.

port on which to depend, in the event of their becoming infirm or destitute, they had a powerful additional motive to save and accumulate; and being excluded from agriculture, they were of necessity compelled to addict themselves, in preference, to commerce. In an age when the profession of a merchant was generally looked upon as something mean and sordid, and when, of course, they had comparatively little competition, they must have made considerable profits; but these have been very greatly exaggerated. It was natural that those indebted to the Jews should represent their gains as enormous; for this inflamed the existing prejudices against them, and afforded a miserable pretext for defrauding them of their just claims. There are a few rich Jews in most of the large cities of Europe; but the majority of that race are, and always have been, as poor as their neighbours.

Let us not, therefore, deceive ourselves by supposing that it is possible for any people to emerge from barbarism, or to become wealthy, populous, and civilized, without the security of property. From whatever point of the political compass we may set out, this is the principle to which we must come at last. Security is indispensable to the successful exertion of the powers of industry. Where it is wanting, it is idle to expect either riches or civilization.[1]

Objections of Rousseau and Beccaria ill founded.

Rousseau and some other sentimental writers have made an objection to the right of property, which has been in some measure sanctioned by the Marquis Beccaria.[2] They allow that the security of property is advantageous for those who possess it; but they contend that it is disadvantageous for those who are poor and destitute. It has condemned, they affirm, the greater portion of mankind to a state of misery, and has provided for the exaltation of the few by the depression of the many! The sophistry of this reasoning is so apparent, as hardly to require being pointed out. The right of property has not made poverty, but it has made wealth. Previously to the institution of this right, those nations which are now most civilized were sunk to the same level of wretchedness and misery as the savages of New Holland and Kamtschatka. All classes have been benefited by the change; and it is mere error and delusion to suppose that the rich have been benefited at the expense of the poor. The right of property gives no advantage to any one man over any other man. It deals out justice impartially to all. It does not say, "labour, and I shall reward you;" but it says, "labour, and I shall take care that none be permitted to rob you of the produce of your exertions." This right has not made all men rich, because it could not make all men frugal and industrious. But it has done more than all the other institutions of society put together to produce that effect. It is not, as it has been sometimes ignorantly or knavishly represented, a bulwark thrown up to protect and secure the property of a few favourites of fortune. It is a rampart raised by society against its common enemies,—against rapine and violence, plunder and oppression. Without its protection, the rich man would become poor, and the poor man would never be able to become rich,—all would sink to the same bottomless abyss of barbarism and poverty. "The security of property has overcome the natural aversion of man from labour, given him the empire of the earth, a fixed and permanent residence, and has implanted in his breast the love of country and of posterity. To enjoy immediately,—to enjoy without labour,—is the natural inclination of every man. This inclination must be restrained; for its obvious tendency is to arm all who have nothing against those who have something. The law which restrains this inclination, and which secures to the humblest individual the quiet enjoyment of the fruits of his industry, is the most splendid achievement of legislative wisdom,—the noblest triumph of which humanity has to boast." (Bentham, *Traité de Législation*, tom. ii. p. 37.)

Security of Property.

Division of labour.

Division of Labour.—The division of labour naturally divides itself into two separate branches: 1*st*, The division of labour among individuals; and, 2*d*, its division among nations.

1. *Individual Division of Labour.*—The division of labour can only be imperfectly introduced in rude societies and thinly-peopled countries. But in every state of society, in the rudest as well as in the most improved, we may trace the operation and effects of this principle. The various physical powers, talents, and propensities with which men are endowed, naturally fit them for different occupations; and a regard to mutual interest and convenience necessarily leads them, at a very early period, to establish a system of barter and a separation of employments. Each individual finds that he may obtain a greater quantity of all sorts of commodities by devoting himself to some particular business, and exchanging his surplus produce for such parts of the produce of other people's labour as he may have occasion for, and they may be disposed to part with, than if he attempted directly to produce all the articles which he consumes. As society advances, this division becomes more and more extended. In process of time, one man becomes a tanner or dresser of skins, another a shoemaker, a third a weaver, a fourth a house-carpenter, a fifth a smith, and so on. Each endeavours to cultivate and bring to perfection whatever talent or genius he may possess for the species of industry in which he is employed. The wealth and comforts of all classes are, in consequence, prodigiously augmented. In a country where the division of labour is carried to a considerable extent, agriculturists do not spend their time in clumsy attempts to manufacture their own produce; and manufacturers cease to interest themselves about the raising of corn and the fattening of cattle. The facility of exchanging is the vivifying principle of industry. It stimulates agriculturists to adopt the best system of cultivation, and to raise the largest crops, because it enables them to exchange whatever portion of the produce of their lands exceeds their own wants for other commodities conducing to their comforts and enjoyments; and it stimulates manufacturers and merchants to increase the quantity and to improve the quality of their goods, that they may obtain a greater supply of raw produce. A spirit of industry is thus universally diffused; and the apathy and languor which characterize a rude state of society entirely disappear.

But it is not the mere facility of exchanging, or the being able to barter the surplus produce of one's own labour for such parts of the produce of other people's labour as we may wish to have and they may choose to part with, that renders the separation of employments of such signal advantage. The introduction of barter and the division of labour not only enables each individual to betake himself in preference to those departments which suit his taste and disposition, but it makes a large addition to the efficacy of ivision of Labour.

---

[1] "Ce n'est que là où les proprietés sont assurés, où l'emploi des capitaux est abandonné au choix de ceux qui les possédent; ce n'est que là, dis-je, que les particuliers seront encouragés à se soumettre aux privations le plus dures pour compenser par leurs épargnes les retards que la profusion du gouvernement peut apporter aux progrès de la richesse national. Si l'Angleterre, malgré ses guerres ruineuses, est parvenue à un haut degré d'opulence; si, malgré les contributions énormes dont le peuple y est chargé, son capital est pourtant accrue dans le silence par l'économie des particuliers, il ne faut attribuer ces effets qu'à la liberté des personnes, et à la sureté des proprietés qui y règnent, plus que dans aucun autre pays de l'Europe, la Suisse excepté." (Storch, *Traité d'Economie Politique*, tom. i. p. 317.)

[2] Speaking of theft, Beccaria calls it "Il delitto di quella infelice parte di uomini a cui *il diritto di proprietà* (*terribile, e forse non necessario diritto*), *non ha lasciato, che una nuda essistenza.*" (*Dei Delitti e delle Pene*, § 22.)

his powers, and enables him to produce a much greater quantity of commodities than he could do did he engage indiscriminately in different employments. Smith, who has treated this subject in the most masterly manner, has classed the circumstances which conspire to increase the productive powers of industry, when labour is divided, under the following heads:—*First*, The increase of the skill and dexterity of the workman; *second*, the saving of time, which is commonly lost in passing from one employment to another; and, *third*, the circumstance of the division of employments having a tendency to facilitate the invention of machines and processes for abridging and saving labour. We shall make a few observations on each of these heads.

ivision of bour in-eases the ill and xterity of e work-an.

1*st*, *As respects the improvement of the skill and dexterity of the labourer*, it is sufficiently plain, that when a person's whole attention is devoted to one branch of business, when all the energies of his mind and powers of his body are made to converge, as it were, to a single point, he must attain to a degree of proficiency in that particular branch, to which no individual engaged in a variety of occupations can be expected to reach. A peculiar play of the muscles, or sleight of hand, is necessary to perform the simplest operation in the best and most expeditious manner; and this can only be acquired by constant practice. Smith has given a striking example, in the case of the nail manufacturer, of the extreme difference between training a workman to the precise occupation in which he is to be employed, and training him to a similar and closely allied occupation. "A common smith," says he, "who, though accustomed to handle the hammer, has never been used to make nails, if, upon some particular occasion, he is obliged to attempt it, will scarce, I am assured, be able to make above two or three hundred nails in a day, and those very bad ones. A smith who has been accustomed to make nails, but whose sole or principal business has not been that of a nailer, can seldom, with his utmost diligence, make more than eight hundred or a thousand nails in a day. But I have seen several boys under twenty years of age, who had never exercised any other trade but that of making nails, who, when they exerted themselves, could make, each of them, upwards of *two thousand three hundred nails in a day*;" or nearly three times the number of the smith who had been accustomed to make them, but who was not entirely devoted to that particular business!

ves time.

2*d*, The influence of the division of labour in preventing that *waste of time in moving from one employment to another*, which necessarily takes place when an individual is engaged in different occupations, is as obvious as its influence in improving the skill and dexterity of the labourer. When the same individual carries on different employments, in different and perhaps distant places, and with different sets of tools, it is plain he must lose a considerable portion of time in passing from one to another. If the different businesses in which a labourer is to be engaged were carried on in the same workshop, the loss of time would be less, but even in that case it would be considerable. "A man," as Dr Smith has justly observed, "commonly saunters a little in changing from one business to another. When he first begins his work, he is seldom keen or hearty; his mind is said not to go along with it, and for some time he rather trifles than applies himself to good purpose. The habit of sauntering, and of indolent, careless application, which is naturally, or rather necessarily, acquired by every country workman, who is obliged to change his work and his tools every half hour, and to apply his hand in twenty different ways almost every day of his life, renders him almost always slothful and lazy, and incapable of any vigorous application, even on the most pressing occasions. Independent, therefore, of his deficiency in point of dexterity, this cause alone must always reduce considerably the quantity of work which he is capable of performing." (*Wealth of Nations*, p. 5.)

Division of Labour.

Facilitates the invention of machines.

3*d*, As respects the influence of the division of employments in *facilitating the invention of machines, and processes for abridging and saving labour*, it is obvious that those engaged in any branch of industry will be more likely to discover easier and readier methods of carrying it on, when their whole attention is devoted exclusively to it, than if they had to attend to a variety of objects. But it is a mistake to suppose, as has been sometimes done, that the inventive genius of workmen and artificers is alone whetted and improved by the division of labour. As society advances, the study of particular branches of science and philosophy becomes the principal or sole occupation of the most ingenious men. Chemistry becomes a distinct science from natural philosophy; the physical astronomer separates himself from the astronomical observer, the political economist from the politician, and each meditating exclusively, or principally, on his peculiar department, attains to a degree of proficiency and expertness in it, which the general scholar seldom or never reaches. And hence, in labouring to promote our own ends, we all necessarily adopt that precise course which is most advantageous for all. Like the different parts of a well-constructed engine, the inhabitants of a civilized country are all mutually dependent on and connected with each other. Without any previous concert, and obeying only the powerful and steady impulse of self-interest, they universally conspire to the same great end, and contribute each in his respective sphere to furnish the greatest possible supply of necessaries, conveniencies, and enjoyments.

Division of labour limited by the extent of the market.

But it is necessary to observe, that the advantages derived from the division of labour, though they may be, and in fact are, partially enjoyed in every country and state of society, can only be reaped in their full extent where there is a great power of exchanging, or an extensive market. Many employments cannot be separately carried on out of the precincts of a large city; and, in all cases, the division becomes more perfect, according as the demand for the produce of the workmen is extended. It is stated by Smith that ten labourers employed in different departments in a pin manufactory can produce 48,000 pins a day; but it is evident that were the demand not sufficiently extensive to take off this quantity, it would be impossible to carry the division so far. The same principle holds in every case. A cotton-mill could not be constructed in a small country, having no intercourse with its neighbours. The demand and competition of Europe and America has been necessary to carry the manufactures of Glasgow, Manchester, and Birmingham to their present state of improvement.

The influence of the division of labour in increasing the quantity and perfection of the products of industry was noticed by several of the writers who preceded Dr Smith, and especially by Harris and Turgot. But neither of these writers has done what Smith did. None of them fully analysed and exhibited its various effects, or showed that the power of engaging in different employments depends on the power of exchanging; and that, consequently, the advantages derived from the division of labour are necessarily dependent on, and regulated by, the extent of the market. This is a principle of great importance, by establishing which Smith shed a new light on the whole science, and laid the foundation of many important practical conclusions. "Présentée de cette manière," says M. Storch, "l'idée de la division du travail étoit absolument neuve; et l'effet qu'elle a fait sur les contemporains de Smith, prouve bien qu'elle l'étoit réellement pour eux. Telle qu'elle se trouve indiquée dans les passages que je viens de citer, elle n'a fait aucune impression. Développée par Smith, cette idée a d'abord saisi tous ses lecteurs; tous en ont senti la vérité et l'importance; et cela suffit pour lui en assurer tout l'honneur, lors même que son génie ait été guidé par les indications de ses devanciers." (Tome vi. p. 10.)

Territorial Division of Labour.

2. *Territorial Division of Labour, or Commerce.*—Besides that sort of division of labour which enables each individual in a limited society to confine himself to a particular employment, there is another and most important branch of the division of labour, which not only enables particular individuals, but the inhabitants of entire districts, and even nations, to addict themselves in preference to certain branches of industry. It is on this *territorial division of labour*, if we may so term it, that the commerce carried on between different districts of the same country, and between different countries, is founded. The various soils, climates, and capacities of production of the different districts of an extensive country, fit them for being appropriated to certain species of industry. A district where coal is abundant, which has an easy access to the ocean, and a considerable command of internal navigation, is the natural seat of manufactures. Wheat and other species of grain are the proper products of rich arable soils; and cattle, after being reared in mountainous districts, are most advantageously fattened in meadows and low grounds. Nothing is more obvious than that the inhabitants of these different districts, by confining themselves to those branches for the prosecution of which they have some peculiar natural capability, must produce an infinitely greater quantity of useful and desirable articles than they could do were they to employ themselves indiscriminately in every different employment. It is impossible to doubt that a vastly greater supply of manufactured goods, corn, and cattle, are produced by the inhabitants of Glasgow, the Carse of Gowrie, and Argyleshire, respectively, confining themselves to manufactures, agriculture, and the rearing of cattle, than if each endeavoured directly to raise these various products.

But it is easy to see that foreign trade, or the territorial division of labour between different and independent countries, contributes to increase the wealth of each in precisely the same manner that the trade between different provinces of the same kingdom contributes to increase their wealth. There is a still greater difference between the productive powers with which nature has endowed different and distant countries than there is between the productive powers of the provinces of the same country. The establishment of a free intercourse between them must, therefore, be proportionally more advantageous. It would evidently cost infinitely more to raise the wines of France or Spain in England, than to make Yorkshire yield the same products as Devonshire. Indeed there are a multitude of products, and some of them of the very greatest utility, that cannot be raised except in particular situations. Were it not for commercial intercourse, we should not be able to obtain the smallest supply of tea, sugar, raw cotton, raw silk, gold bullion, and a thousand other equally useful and valuable commodities. Providence, by giving different soils, climates, and natural productions to different countries, has evidently provided for their mutual intercourse and civilization. By permitting the people of each to employ their capital and labour in those departments in which their geographical situation, the physical capacities of their soil, their national character and habits, fit them to excel, foreign commerce has a wonderful influence in multiplying the productions of art and industry. When the freedom of commerce is not restricted, each country necessarily devotes itself to such employments as are most beneficial for itself. This pursuit of individual advantage is admirably connected with the good of the whole. By stimulating industry, by rewarding ingenuity, and by using most efficaciously the particular powers bestowed by nature, commerce distributes labour most effectively and economically; while, by increasing the mass of necessary and useful products, it diffuses opulence, and binds together the universal society of nations by the common and powerful ties of mutual interest and reciprocal obligation. Commerce enables each particular state to profit by the inventions and discoveries of every other state. It creates new tastes and new appetites, and it also gives the means and the desire of gratifying them. The progress of domestic industry is accelerated by the competition of foreigners. Commerce has either entirely removed, or greatly weakened, a host of unworthy prejudices. It has shown that nothing can be more illiberal and absurd than that once prevalent dread of the progress of others in wealth and civilization; and that the true glory and real interest of each particular people will be more certainly advanced by endeavouring to emulate and outstrip its neighbours in the career of science and civilization, than by labouring to attain a barren pre-eminence in the bloody and destructive, though necessary, art of war.

Territorial Division of Labour.

Effect of the territorial division of labour in augmenting national wealth.

The influence of commerce in giving increased efficacy to labour, and augmenting national wealth, may be easily illustrated. Thus, in the case of the intercourse, or territorial division of labour, carried on between England and Portugal, our superior wool, and our command of coal, skilful workmen, improved machinery, and of all the instruments of manufacturing industry, enable us to produce cloth at a much cheaper rate than the Portuguese; but, on the other hand, the soil and climate of Portugal being peculiarly favourable for the cultivation and growth of the grape, she is able to produce wine at an infinitely less cost than it can be produced here. And hence it is obvious, that England, by confining herself to the manufacture of cloth, in which she has a natural advantage, and exchanging it with the Portuguese for wine, will obtain a vastly larger supply of that commodity than if she attempted to cultivate the grape at home; and Portugal, by exchanging her wine for the cloth of England, will obtain a much greater quantity of cloth than if she attempted to counteract the intention of nature, by converting a portion of her capital and industry from the raising of wine, in which she has an advantage, to the manufacture of cloth, in which the advantage is on the side of another.

Sophism of the French economists on the subject of commerce.

What has been already stated is sufficient to expose the sophism of the French economists, who contended, that as an equivalent must be always given for commodities brought from abroad, it is impossible foreign commerce should be a means of increasing wealth. How, they asked, can the wealth of a country be increased by giving equal values for equal values? They admitted, that commerce might be the means of making a *better distribution* of the wealth of the world; but as it did nothing more than exchange one sort of wealth for another, they denied that it could make any addition to its amount. At first sight, this sophistical and delusive statement appears sufficiently conclusive; but a very few words will be sufficient to demonstrate its fallacy. The advantage of commerce does not consist in its enabling either of the parties who carry it on to obtain articles of greater value than those they give in exchange. It may have cost as much to produce the cloth with which the English merchant purchases the wine of Portugal, as it did to produce the latter, or it may have cost more. But then it must be observed, that in making the exchange, the value of the wine is estimated by what it takes to produce it in Portugal, which has peculiar capabilities for that species of industry, and not by what it would take to produce it in England were the trade put an end to; and, in like manner, the value of the cloth is estimated by what it takes to produce it in England, and not by what it would take to produce it in Portugal. The advantage of the intercourse consists in this, that it enables each country to obtain commodities, for the production of which it has no natural capability, and which it would, therefore, cost vastly more to produce directly at home, at the price required to produce them in the most favourable circumstances, and with the least possible expense. The gain of the one party is not the loss of the other. Both benefit by the intercourse; for erritorial vision of abour.

it enables both to save labour and expense in the production of commodities, so that the wealth of the two countries is not only better distributed, but is also greatly increased, by the territorial division of labour established between them.

To set this important principle in a clearer point of view, let it be supposed that in England a given number of men can, in a given time, manufacture 10,000 yards of cloth and raise 1000 quarters of wheat, and that the same number of men can, in a given time, manufacture in Poland 5000 yards of cloth and raise 2000 quarters of wheat. It is plain, that the establishment of a free intercourse between the two countries would, in these circumstances, enable England, by manufacturing cloth and exporting it to Poland, to obtain *twice* the quantity of corn in exchange for a given outlay of capital and labour that she would obtain in return for the same outlay on cultivation at home; and Poland would, on her part, be enabled to obtain *twice* as much cloth in exchange for her corn as she would have done had she attempted directly to manufacture it. How ridiculous then to contend, that commerce is not a means of adding to the efficacy of labour, and, consequently, of increasing wealth! Were the intercourse between England and Portugal and the West Indies put an end to, it would require, at the very least, a hundred, or perhaps a thousand times the expense to produce port wine, sugar, and coffee, directly in this country, that it does to produce the equivalents sent to Portugal and the West Indies in exchange for them. And no outlay, however great, could directly supply us with teas, spices, and fifty other most important articles.

"The commerce of one country with another is merely an extension of that division of labour by which so many benefits are conferred on the human race. As the same country is rendered richer by the trade of one province with another; as its labour becomes thus infinitely more divided and more productive than it could otherwise have been; and as the mutual interchange of all those commodities which one province has and another wants, multiplies the accommodations and comforts of the whole, and the country becomes thus in a wonderful degree more opulent and happy; so the same beautiful train of consequences is observable in the world at large, that vast empire of which the different kingdoms may be regarded as the provinces. In this magnificent empire, one province is favourable to the production of one species of produce, and another province to another. By their mutual intercourse, mankind are enabled to distribute their labour as best fits the genius of each particular country and people. The industry of the whole is thus rendered incomparably more productive; and every species of necessary, useful, and agreeable accommodation is obtained in much greater abundance, and with infinitely less expense." (Mill's *Commerce Defended*, p. 38.)

To enter into a more enlarged discussion of this interesting and important subject, would be inconsistent alike with the objects and limits of this article. In the articles on Colonies, and the Corn Trade and Corn Laws, we have examined the policy of the restrictions on the colonial and corn trades; and in the article Exchange we have pointed out the circumstances which regulate the importation and exportation of the precious metals; and have shown, that, instead of the excess of exports over imports being any criterion of an advantageous commerce, it is quite the reverse, and that it is by the excess of the value of the imports over that of the exports that the gain of the merchants, and consequently of the community, is to be estimated. In the fourth book of the Wealth of Nations, Dr Smith has examined and refuted the various arguments in favour of restrictions on commerce, in the most able and masterly manner, and with an amplitude of illustration which leaves nothing to be desired. A very complete exposure of the sophisms of the French economists, on the subject of commerce, may be found in the pamphlets of Mr Mill (Commerce Defended) and Colonel Torrens (Economists Refuted), in answer to Mr Spence's pamphlet entitled Britain Independent of Commerce. And ample information on most points relating to the practice, theory, and history of commerce, will be found in the Commercial Dictionary, by the author of this article.

Territorial Division of Labour.

Money.

When the division of labour was first introduced, barter was the only method of exchanging commodities. But according as society advanced, as the division of employments was extended, and exchanges became more numerous, the advantage of using one article as a common medium of exchange,—as an equivalent for all other commodities, and as a standard by which to ascertain their values,—soon became obvious. But this is a subject of which we have elsewhere treated at considerable length; and we beg to refer the reader, for a full investigation of the nature and functions of the common medium of exchange, to the articles Money, and Paper Money and Banks, in this work.

Accumulation and employment of capital.

Accumulation and Employment of Capital.—Capital may be defined to be "*that portion of the produce of labour saved from immediate consumption, which is employed to maintain productive labourers, or to facilitate production.*" Its accumulation and employment is indispensably necessary to the successful prosecution of almost every branch of industry. Without that species of capital which chiefly consists of tools and engines, and which has been denominated *fixed*, labour could never be rendered considerably productive; and without that species of capital which chiefly consists of the food and clothes required for the consumption of the labourer during the time he is employed in production, and which has been denominated *circulating*, he never could engage in any undertaking which did not yield an almost immediate return. An agricultural labourer, for example, might have an ample supply of carts and ploughs, of oxen and horses, and generally of all the instruments and animals used in his department of industry; but were he destitute of *circulating* capital, or of food and clothes, he would be unable to avail himself of their assistance, and, instead of tilling the ground, would have to betake himself immediately to some species of appropriative industry. And, on the other hand, supposing the husbandman to be abundantly supplied with provisions, what could he do without the assistance of *fixed* capital, or tools? What could the most skilful agriculturist perform without his spade and his plough? a weaver without his loom? or a house-carpenter without his saw, his axe, and his planes? The accumulation and employment of fixed and circulating capital is indispensable to the elevating of every nation in the scale of civilization. And it is only by their conjoined and powerful operation that wealth can be largely produced and universally diffused.

The division of labour is a consequence of the previous accumulation of capital. Before labour can be divided, "A stock of goods of different kinds must be stored up somewhere, sufficient to maintain the labourer, and to supply him with the materials and tools of his work. A weaver cannot apply himself entirely to his peculiar business, unless there is beforehand stored up somewhere, either in his own possession or in that of some other person, a stock sufficient to maintain him, and supply him with the materials and tools of his work, till he has not only completed, but sold his web. This accumulation must evidently be previous to his applying his industry for so long a time to such a peculiar business." (*Wealth of Nations*, p. 119.)

As the accumulation of stock must precede the division of labour, so its subsequent division can only be extended as capital is more and more accumulated. Accumulation and division act and re-act on each other. The quantity of raw materials which the same number of people can work up increases in a great proportion as labour comes to be more and more subdivided; and according as the operations of each workman are reduced to a greater degree of identity and simplicity, he has, as already explained, a greater chance of discovering machines and processes for facilitating and abridging labour. The quantity of industry, therefore, not only increases in every country with the increase of the stock or capital which sets it in motion, but, in consequence of this increase, the division of labour becomes extended, new and more powerful implements and machines are invented, and the same amount of labour is made to produce a much greater quantity of commodities.

Besides its effect in enabling labour to be divided, capital contributes to facilitate labour and produce wealth, in the three following ways:

Modes in which the employment of capital facilitates labour.

First.—It enables work to be executed that could not be executed, or commodities to be produced that could not be produced, without it.

Second.—It saves labour in the production of almost every species of commodities.

Third.—It enables work to be executed better, as well as more expeditiously.

1*st*, It enables us to produce commodities that could not be produced without it.

With regard to the first of those modes in which we are benefited by the employment of capital, or to its *enabling commodities to be produced that could not be produced without it*, it is plain that the production of such commodities as require a considerable period for their completion, could not be attempted unless a stock of circulating capital, or of food and clothes sufficient for the maintenance of the labourer while employed on them, were previously provided. But the employment of fixed is frequently as necessary to production as the employment of circulating capital. It would be impossible to produce a pair of stockings without the aid of wires; and though the ground might be cultivated without the aid of a plough, it could not be cultivated without the aid of a spade or hoe. If we run over the vast catalogue of the various arts practised in a polished and civilized country, it will be found that there are very few that can be carried on by the mere employment of the fingers, or tools with which man is furnished by nature. It is almost always necessary to provide ourselves with the results of previous industry, and to strengthen our feeble hands, by arming them, if we may so speak, "with the force of all the elements."

2*d*, It saves labour in the production of commodities.

In the *second* place, the employment of capital not only enables many species of commodities to be produced that could not be produced without its co-operation, but it also enables *labour to be saved in the production of many others*, and, by lowering their price, brings them within the reach of a far greater number of consumers. We have been so long accustomed to make use of the most powerful machines, that it requires a considerable effort of abstraction to render ourselves fully aware of the extent of the advantages we derive from them. But if we compare the arts practised alike by civilized man and the savage, we cannot fail to be convinced, that it is to the employment of fixed capital that we owe a very large portion of our superior comforts and enjoyments. Consider the advantages derived from the employment of the lower animals, which, in an economical point of view, are to be regarded only as machines! Consider the advantages derived from the formation of roads, bridges, harbours, and canals—the effect they have had in facilitating the conveyance of commodities, in distributing them most advantageously, and in reducing their price to the consumer! Consider the advantages derived from the construction of ships, and the improvement of navigation! But it is in vain to attempt even to glance at the numberless benefits which the employment of tools and machines has conferred on society, by cheapening and multiplying necessaries, conveniencies, and luxuries. It is by their means that our fields are cultivated, our houses constructed, our clothes manufactured, our ships built, and the treasures of knowledge and of art conveyed from one hemisphere to another! If we consult the history of the human race—if we trace their slow and gradual advancement from barbarism to refinement—we shall be convinced that their progress from their lowest and most abject, to their highest and most polished, state, has been always accompanied, and chiefly promoted, by the accumulation of fresh capital, and the invention and improvement of tools and engines.

3*d*, It enables us to execute work better, as well as more expeditiously.

The *third* advantage derived from the employment of capital consists in the circumstance of its enabling work to be done *better*, as well as more expeditiously, than it could be done without it. Cotton, for example, might be spun by the hand; but the admirable machinery invented by Hargreaves, Arkwright, and others, has not only enabled a hundred or a thousand times more yarn to be produced than could be spun by means of a common spindle, but it has also improved its quality, and given to it a degree of fineness, and of evenness, or equality, in its parts, which was never previously attained. It would require a painter months, or it might be years, to paint with a brush the cottons or printed cloths used in the hanging of a single room; and it would be very difficult, if not impossible, for the best artist to give the same perfect identity to his figures that is given to them by the admirable machinery now used for that purpose. Not to mention the other and more important advantages derived from the invention of moveable types and printing, it is certain that the most perfect manuscript—one on which years of patient and irksome labour have been expended—is unable, in point of delicacy and correctness, to match a well-printed work, executed in the hundredth part of the time, and at a hundredth part of the expense, required to copy the manuscript. The great foreign demand for English manufactured goods results no less from the superiority of the manufacture, than from their greater cheapness; and for both these advantages we are principally indebted to the excellence of our machinery.

The power to employ labour depends on the amount of capital.

There are other considerations which equally illustrate the extreme importance of the accumulation and employment of capital. The produce of the labour of a nation cannot be increased otherwise than by an increase in the number of its labourers, or of their productive powers. But without an increase of capital, it is in most cases impossible to employ another workman with advantage. If capital be not augmented, and if the food and clothes destined for the support of the labourers, and the tools and machines with which they are to operate, be all required for the maintenance and efficient employment of the labourers in existence at any given period, there can be no additional demand for them. In such circumstances the rate of wages cannot rise; and if the number of inhabitants be increased, they must be worse provided for. Neither can the productive powers of the labourer be augmented, without a previous increase of capital. It is only by the better education and training of workmen, by the greater subdivision of their employments, or by an improvement of machinery, that their productive powers can ever be materially increased. But in almost all these cases additional capital is required. It is only by its means that workmen can be better trained, or that the undertaker of any work can either provide his workmen with better machinery, or make a more proper distribution of employment among them. When the work to be done consists of a number of parts, to keep every man constantly employed in a particular part requires a much larger stock than where every man is occasionally employed in different parts of the work. "When," says Dr Smith, "we compare the state of a nation at two different periods, and find that the annual produce of its land and labour is evidently greater at the latter than at the former,—

Employment of Capital.

that its lands are better cultivated, its manufactures more numerous and more flourishing, and its trade more extensive,—we may be assured that its capital must have increased during the interval between these two periods, and that more must have been added to it by the good conduct of some, than had been taken from it, either by the private misconduct of others, or by the public extravagance of government." (*Wealth of Nations*, p. 152.) It is therefore apparent that no country can ever reach the stationary state, so long as she continues to add to her capital. So long as she does this, she will have an increasing demand for labour, and will be constantly augmenting the mass of necessaries, luxuries, and conveniencies, and consequently also the numbers of her people. But with every diminution of the previous rate at which capital had been accumulating, the demand for labour will decline. When no additions are made to capital, no more labour will be, or, indeed, can be employed. And should the national capital be diminished, the condition of the great body of the people would be greatly deteriorated—for the wages of labour would be reduced, and pauperism, with its attendant train of vice, misery, and crime, would spread its ravages throughout the largest portion of society.

ccumula- ion of ca- ital.

dvantage f high rofits.

Having thus endeavoured to point out the vast importance of the employment of capital, and the manner in which it co-operates in facilitating production, we proceed to explain the circumstances most favourable for its accumulation. Now, as capital is nothing but the accumulated produce of previous industry, it is evident that its increase will be most likely to be most rapid where industry is most productive, or, in other words, where *the profits of stock are highest.*[1] The man who can produce a bushel of wheat in three days, may accumulate twice as fast as the man who, either from a deficiency of skill, or from having to cultivate a bad soil, is forced to labour six days to produce the same quantity; and the capitalist who can invest stock so as to yield him a profit of ten per cent., has it equally in his power to accumulate twice as fast as he who can only obtain five per cent. for his capital. Experience, too, shows, that while high profits afford greater means of saving, they act as incentives to accumulation. Hence it is found that, in those countries most rapidly increasing in wealth and population, the rate of profit is always comparatively high. Thus in the United States the rate of profit is usually twice as high as in Great Britain or France; and it is to this that the more rapid advancement of the former in wealth and population is entirely to be ascribed. We do not mean to say that high profits are necessarily and in every instance accompanied by a great degree of prosperity. Countries with every other advantage for the profitable employment of industry and stock, may be subjected to a despotical government, which does not respect the right of property; and the want of adequate security thence resulting may be sufficient to paralyse all the exertions of those who are otherwise placed in the most favourable situation for the accumulation of capital. But we have no hesitation in laying it down as a principle which holds in every case, and from which there is really no exception, that, if the governments of any two or more countries be about equally liberal, and property in each about equally well secured, their comparative prosperity will depend on the rate of profit. Wherever profits are high, there is a great demand for labour, and the society rapidly augments both in population and riches. On the other hand, wherever they are low, the demand for labour is proportionally reduced, and the progress of society rendered so much the slower.

Accumulation of Capital.

Parsimony necessary to accumulation.

But however high the rate of profit, had men always *lived up to their incomes*, that is, had they always consumed the whole produce of their industry in the gratification of their immediate wants and desires, it is obvious there could have been no such thing as capital in the world. High profits are advantageous, because they afford the means of amassing capital; but something more is necessary to make us use these means, and this is the accumulating principle. The desire implanted in the breast of every individual of rising in the world, and improving his condition, has prompted mankind to save a portion of their income, or of the produce of their industry, from immediate consumption, and to set it apart as a fund, or capital, to assist them in their future undertakings. It is to this principle, therefore, or rather to its effect, parsimony, that we owe capital; and it is to capital that we owe almost all our comforts and enjoyments. Without its assistance and co-operation, labour could not have been divided; arts could not have made any progress; and mankind must have continued to shelter themselves, as in the earliest ages, in caves and forests, and to clothe themselves with the skins of wild animals. All the accumulated riches of the world,—the cities which cover its surface, the ships which traverse its seas, and the innumerable variety of improvements,—owe their origin to this principle,—to the desire to rise in the world, and consequently to save and amass.

It has been wisely ordered, that this principle should be as powerful as it is advantageous. "With regard to profusion," says Smith, "the principle which prompts to expense is the passion for present enjoyment; which, though sometimes violent, and very difficult to be restrained, is in general only momentary and occasional. But the principle which prompts to save is the desire of bettering our condition; a desire which, though generally calm and dispassionate, comes with us from the womb, and never leaves us till we go into the grave. In the whole interval which separates these two moments, there is scarce perhaps a single instance in which any man is so perfectly and completely satisfied with his situation as to be without any wish of alteration, or improvement of any kind. An augmentation of fortune is the means by which the greater part of men propose and wish to better their condition. It is the means the most vulgar and the most obvious; and the most likely way of augmenting their fortune is to save and accumulate some part of what they acquire, either regularly and annually, or upon some extraordinary occasion. Though the principle of expense, therefore, prevails in almost all men upon some occasions, and in some men upon almost all occasions, yet in the greater part of men, taking the whole course of their life at an average, the principle of frugality seems not only to predominate, but to predominate very greatly." (*Wealth of Nations*, p. 151.)

It is this principle which carries society forward. The spirit of parsimony, and the efforts which the frugal and industrious classes make to improve their condition, in most instances balance not only the profusion of individuals, but also the more wasteful profusion and extravagance of government. The spirit of economy has been happily compared by Smith to the unknown principle of animal life—the *vis medicatrix naturæ*—which frequently restores health and vigour to the constitution, in spite both of disease and of the absurd prescriptions of the physician.

But, however great the capacity of the principle of accumulation to repair the waste of capital, we must take care not to fall into the error of supposing, as very many have done, that its operations are in all cases promoted by a

---

[1] To avoid all chance of misconception, it is necessary to observe, that this refers to *nett* profit, or to the sum which remains to the capitalist after all his outgoings are compensated, including therein a sum sufficient to insure his capital against risk, and to make up for whatever may be peculiarly disagreeable in his business.

Accumulation of Capital.

large public expenditure. To a certain extent, indeed, this is true. A moderate increase of taxation has the same effect on the habits and industry of a nation, that an increase of his family, or of his necessary and unavoidable expenses, has upon a private individual. Man is not influenced solely by hope; he is also powerfully operated upon by fear. Taxation brings the latter principle into the field. To the desire of rising in the world, inherent in the breast of every individual, an increase of taxation superadds the fear of being cast down to a lower station, of being deprived of conveniencies and gratifications which habit has rendered almost indispensable; and the combined influence of the two principles produces efforts that could not be produced by the unassisted agency of either. They stimulate individuals to endeavour, by increased efforts of industry and economy, to repair the breach taxation has made in their fortunes; and it not unfrequently happens that their efforts do more than this, and that consequently the national wealth is increased through the increase of taxation. But we must be on our guard against the abuse of this doctrine. To render an increase of taxation a cause of greater exertion, economy, and invention, its increase should be slow and gradual; and it should never be carried to such a height as to incapacitate individuals from meeting the sacrifices it imposes on them, by such a moderate degree of increased exertion and economy as it may be in their power to make, without requiring any very violent change in their habits. The increase of taxation must not be such as to render it impracticable to overcome its influence, or to induce the belief that it is impracticable. Difficulties that are seen to be surmountable sharpen the inventive powers, and are readily grappled with; but an apparently insurmountable difficulty, or such an excessive weight of taxation as it was deemed impossible to meet, would not stimulate, but destroy exertion. Instead of producing new efforts of ingenuity and economy, it would produce only despair. Whenever taxation becomes so heavy that the produce it takes from individuals can no longer be replaced by fresh efforts, these efforts uniformly cease to be made; the population becomes dispirited, industry is paralysed, and the country rapidly declines.

Ambition to rise is the animating principle of society. Instead of remaining satisfied with the condition of their fathers, the great object of mankind in every age has been to rise above it, to elevate themselves in the scale of wealth. To continue stationary, or to retrograde, is not natural to society. Man from youth grows to manhood, then decays and dies; but such is not the destiny of nations. The arts, sciences, and capital of one generation become the patrimony of that which succeeds them, and in their hands are augmented and rendered more efficient; so that, if not counteracted by the want of security, or by other adventitious causes, the principle of improvement would always operate, and would secure the constant advancement of nations in wealth and population.

To this same principle we owe the discovery and improvement of machinery. In every period, men endeavour to increase their productive powers, and improve their condition, by availing themselves of natural agents, and making them assist in performing tasks which must otherwise be performed by the hand only. The savage employs a club and a sling to facilitate the acquisition of game; and the same principle which prompted him to construct and use these rude instruments, never ceases to operate. It is always producing some new improvement, and, in an advanced and refined period, substitutes ships for canoes, muskets for slings, steam-engines for clubs, and cotton-mills for distaffs. "The hand of man," says Colonel Torrens, "is not armed with any efficient natural instrument, such as the beak of the bird, or the claw of the quadruped, for operating directly upon the materials presented to him; but it is admirably adapted for receiving and applying artificial implements, and for employing the powers of one substance to produce the desired changes in another. Hence almost all the grand results in manufacturing industry are brought about by means of capital. Throughout the world there are no very striking inequalities in the muscular force by which direct labour is performed; and it is mainly owing to the differences in the quantity of capital, and in the skill with which it is applied, that in one country man is found naked and destitute, and that in another all the rude productions of the earth, and all the forces of nature, are made to contribute to his comfort, and to augment his power." (*On the Production of Wealth*, p. 89.)

Accumulation of Capital.

SECT. III.—*Different Employments of Capital and Industry.—Manufactures and Commerce shown to be equally advantageous as Agriculture.—Rate of Profit true Test of Individual and Public Advantage.*

Different employments of capital and industry.

In the previous section, we endeavoured to show that the increase and diminution of capital is the pivot on which national prosperity principally hinges; that an increase of capital proportionally increases the means of supporting and employing labour, and that its diminution can hardly fail to lessen the comforts and enjoyments, and perhaps also the necessaries, of the productive classes, and to spread poverty and misery throughout the land; and we also endeavoured to show that the rise and decline of the rate of profit is the great cause of the increase and diminution of capital. But if such be the case, it seems impossible not to conclude, that such employments as yield the greatest profit, or in which industry is most productive, are the most advantageous. Dr Smith, however, with Mr Malthus and others, have objected to this standard. They allow that if two capitals yield equal profits, the employments in which they are engaged are equally beneficial to their possessors; but they contend, that if one of these capitals be employed in agriculture, it will be productive of greater public advantage. We believe, however, notwithstanding the deference due to the authorities referred to, that this opinion rests on no good foundation; and that the average rate of profit is the test by which we should always judge which employment is most and which is least advantageous.

A capital may be employed in *four* different ways, viz. *first*, in the production of raw products; or, *secondly*, in manufacturing and preparing these raw products for use and consumption; or, *thirdly*, in transporting the raw and manufactured products from one place to another, according to the demand; or, *fourthly*, in dividing particular portions of either into such smaller parcels as may suit the convenience of those who want them. The capital of all those who undertake the improvement or cultivation of lands, mines, or fisheries, is employed in the first of these ways; that of all master manufacturers in the second; that of all wholesale merchants in the third; and that of all retailers in the fourth. It is difficult to conceive that a capital should be employed in any way which may not be classed under some one or other of these heads.

Employment of capital in agriculture.

It is unnecessary to enlarge on the importance of employing capital in the acquisition of raw produce, and especially in the cultivation of the soil. It is from the latter, including therein mines and fisheries, that the matter of all commodities that minister to our necessities, comforts, or enjoyments, must be originally derived. The industry which appropriates the raw or spontaneous products of the earth preceded every other. But these are always extremely limited. And it is by agriculture only, that is, by the united application of immediate labour and of capital to the cultivation of the ground, that large supplies of those species of raw produce which form the principal part of the food of man can be obtained. It is not quite certain whether any of the principal bread corns, as wheat, barley, rye, oats, &c. have been discovered growing spontaneously. But although this must originally have been the case, their extreme scarcity, and the labour required to raise them in considerable quantities, prove beyond all question that it is to agriculture we are almost exclusively indebted for them. The transition from the pastoral to the agricultural mode of life is decidedly the most important step in the progress of society. Whenever, indeed, we compare the quantity of food, and of other raw products, obtained from a given surface of a well-cultivated country, with those obtained from the same extent of an equally fertile country, occupied by hunters or shepherds, the powers of agricultural industry in increasing useful productions appear so extraordinary, that we cease to feel surprise at the preference which has been so early and generally given to agriculture over manufactures and commerce; and are disposed to subscribe without hesitation to the panegyric of Cicero when he says, "*Omnium autem rerum ex quibus aliquid acquiritur, nihil est agricultura melius, nihil uberius, nihil dulcius, nihil homine libero dignius.*"

Employ-
ment of ca-
pital in ma-
nufacturing
ndustry.

But are there any really just grounds for this preference? Are not manufactures and commerce as advantageous as agriculture? It is plain that without agriculture we should never possess any considerable supply of the materials out of which food and clothes are made; but is it not equally plain, that without a knowledge of the arts by which they are converted into food and clothes, the largest supply of these materials could be of little or no service? The labour of the miller and baker is as necessary to the production of bread, as that of the husbandman who tills the ground. It is the business of the agriculturist to raise flax and wool; but if the industry of the spinner and weaver did not give them utility, and fit them for being made a comfortable dress, they would be nearly, if not entirely, worthless. Without the labour of the miner who digs the mineral from the bowels of the earth, we should be destitute of the matter of which many of our most useful implements and splendid articles of furniture are made; but if we compare the ore when dug from the mine with the finished articles, we shall certainly be convinced that the labour of the purifiers and refiners of the ore, and of the artists who afterwards converted it to useful purposes, has been quite as advantageous as the industry of the miner.

Necessity

acturing
ndustry to
he im-
rovement
n agricul-
ure.

But not only is it certain that manufacturing industry, or that species of industry which fits and adapts the raw produce of nature to our use, is requisite to render its acquisition of any considerable value; but it is also certain, that without manufacturing industry this very raw produce could never have been obtained in any considerable quantity. The mechanic who fabricates the plough contributes as efficaciously to the production of corn as the husbandman who guides it. But plough-wrights, mill-wrights, smiths, and all those artisans who prepare tools and machines for the husbandman, are really manufacturers, and differ in no respect from those employed to give utility to wool and cotton, except that they work on harder materials. Tools and machines are the produce of the industry of the tool and engine manufacturer; and without their aid it is impossible that agricultural, or any other sort of labour, should ever become considerably productive.

"Distinguer," says the Marquis Garnier, "le travail des ouvriers de l'agriculture d'avec celui des autres ouvriers, est une abstraction presque toujours oiseuse. Toute richesse, dans le sens dans lequel nous la concévons, est nécessairement le résultat de ces deux genres de travail, et la consommation ne peut pas plus se passer de l'un que de l'autre. Sans leur concours simultané il ne peut y avoir de chose consommable, et par conséquent point de richesse. Comment pourrait-on donc comparer leurs produits respectifs, puisque, en séparant des deux espèces de travail, on ne peut plus concévoir de véritable produit, de produit consommable et ayant une valeur réele? La valeur du blé sur pied résulte de l'industrie du moissonneur qui récueillera, du batteur qui le séparera de la paille, du méunier et du boulanger qui le convertiront successivement en farine et en pain, tout comme elle résulte du travail du laboureur et du sémeur. Sans le travail du tisserand le lin n'aurait pas plus le droit d'être compté au nombre des richesses que l'ortie, ou tout autre végétal inutile. A quoi pourrait-il donc servir de rechercher lequel de ces deux genres de travail contribue le plus à l'avancement de la richesse nationale? N'est-ce pas comme si l'on disputait pour savoir lequel, du pied droit ou du pied gauche, est plus utile dans l'action de marcher?"[1]

No real difference between agricultural and manufacturing industry.

In fact, there is not at bottom any real distinction between agricultural and manufacturing industry. It is, as already seen, a vulgar error to suppose that the operations of husbandry add anything to the stock of matter already in existence. All that man can do, and all that he ever does, is merely to give to matter that particular form or shape which fits it for his use. But it was contended by Quesnay and the French economists, and their opinions have in this instance been espoused by Smith, that the labour of the husbandman in adapting matter to our use is powerfully facilitated by the vegetative powers of nature, while the labour of the manufacturer has to perform everything itself without any such co-operation. "No equal quantity of productive labour, employed in manufactures," says Dr Smith, "can ever occasion so great a reproduction (as if it were employed in agriculture). In them nature does *nothing,* man does *all;* and the reproduction must always be in proportion to the strength of the agents that occasion it. The capital employed in agriculture, therefore, not only puts into motion a greater quantity of productive labour than any equal capital employed in manufactures, but, in proportion, too, to the quantity of productive labour which it employs, it adds a much greater value to the annual produce of the land and labour of the country, to the real wealth and revenue of its inhabitants. Of all the ways in which a capital can be employed, it is by far the most advantageous to the society." (*Wealth of Nations,* p. 162.)

Opinion of Dr Smith respecting the superior productiveness of agriculture.

Error of this opinion.

This is perhaps the most objectionable passage in the Wealth of Nations; and it is really astonishing that so acute and sagacious a reasoner as Smith should have maintained a doctrine so manifestly erroneous. It is unquestionably true, that nature powerfully assists the labour of man in agriculture. The husbandman prepares the ground for the seed, and deposits it there; but it is nature that unfolds the germ, that feeds and ripens the growing plant, and brings it to maturity. But does not nature do as much for man in every other department of industry? The powers of water and of wind, which move our machinery, support our ships, and impel them over the deep,—the pressure of the atmosphere, and the elasticity of steam, which enable us to work the most stupendous engines,—are they not spontaneous gifts of nature? In fact, the advantage of machinery consists exclusively in its having enabled us to press the powers of nature into our service, and to make them perform the principal part of what would otherwise have been wholly the work of man. In navigation, for example, is it possible to doubt, that the powers of nature,—the buoyancy of the water, the impulse of the wind, and the polarity of the magnet,—contribute fully as much as

Nature cooperates with man in manufactures and commerce.

Different Employments of Capital and Industry.

the labour of the sailor to waft our ships from one hemisphere to another. In bleaching and fermentation the whole processes are carried on by natural agents. And it is to the influence of heat in softening and melting metals, preparing food, and warming houses, that we owe many of our most powerful and convenient instruments, and that these northern climates have been made to afford a comfortable habitation. So far, indeed, is it from being true that nature does much for man in agriculture, and nothing in manufactures, that the fact is more nearly the reverse. There are no limits to the bounty of nature in manufactures, but there are limits, and those not very remote, to her bounty in agriculture. The greatest possible amount of capital may be expended in the construction of steam-engines, or of any other sort of machines, and after they have been multiplied to infinity, the last will be as powerful and efficient in saving labour and producing commodities as the first. Such, however, is not the case with the soil. Lands of the first quality are speedily exhausted; and it is impossible to apply capital indefinitely, even to the best soils, without obtaining a progressively diminishing rate of profit. The rent of the landlord is not, as Smith supposed, the recompense of the work of nature remaining, after all that part of the product is deducted which can be regarded as the recompense of the work of man. But it is, as will be hereafter shown, the excess of produce obtained from the best soils in cultivation, over that which is obtained from the worst; it is a consequence, not of the increase, but of the diminution of the productive power of the labour employed in agriculture.

Employment of capital in commercial industry.

But if the giving utility to matter be, as it really is, the exclusive object of every species of productive industry, it is plain that the capital and labour employed in carrying commodities from where they are produced to where they are to be consumed, and in dividing them into minute portions, so as to suit the wants of the consumers, are really as productive as if they were employed in either agriculture or manufactures. The miner gives utility to matter, to coal, for example, by bringing it from the bowels of the earth to its surface; but the merchant, or carrier, who transports this coal from the mine whence it has been dug, to the city or place where it is to be burned, gives it a further and perhaps a more considerable value. We do not owe our fires exclusively to the miner or coal-merchant. They are the result of the conjoint operations of both, and also of the operations of all those who have furnished them with the tools and implements used in their respective employments.

Advantage of retail dealers.

Not only, however, must commodities be brought from where they are produced to where they are to be consumed, but it is further necessary that they should be divided into such small and convenient portions, that each individual may be able to purchase the precise quantity he is desirous to obtain. "If," says Dr Smith, "there was no such trade as a butcher, every man would be obliged to purchase a whole ox or a whole sheep at a time. This would generally be inconvenient to the rich, and much more so to the poor. If a poor workman was obliged to purchase a months' or six months' provisions at a time, a great part of the stock which he employs as a capital in the instruments of his trade, or in the furniture of his shop, and which yields him a revenue, he would be forced to place in that part of his stock which is reserved for immediate consumption, and which yields him no revenue. Nothing can be more convenient for such a person than to be able to purchase his subsistence from day to day, or even from hour to hour, as he wants it. He is thereby enabled to employ almost his whole stock as a capital. He is thus enabled to furnish work to a greater value, and the profit which he makes by it in this way much more than compensates the additional price which the labour of the retailer imposed upon the goods. The prejudices of some political writers against shopkeepers and tradesmen are altogether without foundation. So far is it from being necessary either to tax them or to restrict their numbers, that they can never be multiplied so as to hurt the public interests, though they may so as to hurt one another. The quantity of grocery goods, for example, which can be sold in a particular town, is limited by the demand of that town and its neighbourhood. The capital, therefore, which can be employed in the grocery trade, cannot exceed what is sufficient to purchase that quantity. If this capital is divided between two different grocers, their competition will obviously tend to make both of them sell cheaper than if it were in the hands of one only; and if it were divided among twenty, their competition would be just so much the greater, and the chance of their combining together in order to raise the price just so much the less. Their competition might perhaps ruin some of themselves; but to take care of this is the business of the parties concerned, and it may safely be trusted to their discretion. It can never hurt either the consumer or the producer; on the contrary, it must tend to make the retailers both sell cheaper and buy dearer than if the whole trade was monopolized by one or two persons. Some of them, perhaps, may occasionally decoy a weak customer to buy what he has no occasion for. This evil is, however, of too little importance to deserve the public attention, nor would it necessarily be prevented by restricting their numbers." (*Wealth of Nations*, p. 160.)

Agriculture, manufactures, and commerce equally advantageous.

Thus it appears that all the modes in which capital can be employed in productive industry, or, in other words, that the raising of raw produce, the fashioning of this raw produce, after it is raised, into useful and agreeable articles, the carrying of the raw and manufactured products from one place to another, and retailing them in such portions as may suit the public demand, are equally advantageous; that is, the capital and labour employed in any one of these departments contributes, equally with that employed in the others, to increase the mass of necessaries, conveniencies, and luxuries. Without a previous supply of raw produce, we should have no manufactures; and without these and commercial industry, the greater part of this raw produce would be entirely worthless, and would neither satisfy our wants nor contribute to our comforts. Manufacturers and merchants are to the body politic what the digestive powers are to the human body. We could not exist without food; but the largest supplies of food cannot lengthen our days when the machinery by which nature prepares and adapts it for our use, and incorporates it with our body, is vitiated and deranged. Nothing therefore can be more silly and childish than the estimates so frequently put forth of the comparative advantages of agricultural, manufacturing, and commercial industry. They are all intimately connected, and depend upon, and grow out of, each other. "Land and trade," to borrow the just and forcible expressions of Sir Josiah Child, "are twins, and have always, and ever will, wax and wane together. It cannot be ill with trade but lands will fall, nor ill with lands but trade will feel it." This reasoning cannot be controverted; and on its authority we are entitled to condemn every attempt to exalt one species of industry, by giving it factitious advantages at the expense of the rest, as being alike impolitic and pernicious. No preference can be given to agriculturists over manufacturers and merchants, or to the latter over the former, without occasioning the most extensively ruinous consequences. Men, in every instance, should be allowed to follow their own inclinations in the employment of their stock and industry. Where industry is free, the interests of individuals can never be opposed to those of the public. Those who succeed best in increasing their own wealth, must necessarily also succeed best in increasing the wealth of the state of which they are subjects.[1]

This mutual dependence of the different branches of industry on each other, and the necessity of their co-operation to enable mankind to make any considerable progress in civilization, have been ably illustrated in an early number of the Edinburgh Review. " It may safely be concluded, that all those occupations which tend to supply the necessary wants or to multiply the comforts and pleasures of human life, are equally productive, in the strict sense of the word, and tend to augment the mass of human riches, meaning, by riches, all those things which are necessary, or convenient, or delightful to man. The progress of society has been productive of a complete separation of employments originally united. At first, every man provided, as well as he could, for his necessities as well as his pleasures, and for *all* his wants as well as *all* his enjoyments. By degrees a division of these cares was introduced; the subsistence of the community became the province of one class, its comforts of another, and its gratifications of a third. The different operations subservient to the attainment of each of these objects were then intrusted to different hands; and the universal establishment of barter connected the whole of these divisions and subdivisions together—enabled one man to manufacture for all, without danger of starving by not ploughing or hunting, and another to plough or hunt for all, without the risk of wanting tools or clothes by not manufacturing. It has thus become as impossible to say exactly who feeds, clothes, or entertains the community, as it would be to say which of the many workmen employed in the manufacture of pins is the actual pin-maker, or which of the farm-servants produces the crop. All the branches of useful industry work together to the common end, as all the parts of each branch cooperate to its particular object. If you say that the farmer feeds the community, and produces all the raw materials which the other classes work upon, we answer, that unless those other classes worked up the raw materials, and supplied the farmer's necessities, he would be forced to allot part of his labour to this employment, whilst he forced others to assist in raising raw produce. In such a complicated system, it is clear that all labour has the same effect, and equally increases the whole mass of wealth. Nor can any attempt be more vain than theirs who would define the particular parts of the machine that produce the motion, which is necessarily the result of the *whole powers combined*, and depends on each particular one of the mutually connected members." (Vol. iv. p. 362.)

Much has been said respecting the extraordinary mortality of large manufacturing establishments. The ready communication of contagion where people are crowded together,—the want of sufficient ventilation,—the confinement of children,—and the positive unhealthiness of some particular processes,—are circumstances from which most writers have been led to infer that the mortality in manufacturing cities *must* be unusually great, without giving themselves the trouble to inquire whether it really was so. The returns under the population acts have shown the fallacy of these opinions. Great Britain was infinitely more of a manufacturing country in 1820 and 1830 than in 1780; but, notwithstanding the vast increase during the intermediate period of what we have been in the habit of considering unhealthy employments, the average mortality in England and Wales during the *five* years ending with 1820, was one in every fifty-five, and during the five years ending with 1830 it was one in every fifty-one, of the existing population, whereas in 1780 it was one in every forty. It may perhaps be said, that this increased healthiness is owing to improvements in agriculture,—to the drainage of bogs and marshes, the inclosure and cultivation of commons and wastes,— and not to the extension of manufactures. But suppose this were admitted, still we should have to inquire what had occasioned these extraordinary improvements in agriculture. And a moment's reflection would suffice to convince us that they have principally resulted from the improvement of manufactures,—from the increased demand of the manufacturing population for the raw produce of the soil. In point of fact, however, it is certain, that much of this diminution of mortality is a direct, and not an indirect, consequence of the improvement and extension of manufactures. Every one knows the vast importance in respect of health, of the people having the means of providing themselves with comfortable clothes at a cheap rate. And this is one of the many advantages which improvements in manufacturing industry bring along with them. The reduction in the price of cotton goods only, occasioned by the greater facility with which they are now produced, has enabled the poorest classes to clothe themselves in a comfortable and elegant dress; and has been productive of an increase of enjoyment, of which it is extremely difficult for us, who have so long experienced its beneficial effects, to estimate the extent.

Manufactures not productive of increased mortality.

Division of labour does not degrade the labourer.

The effect of the extreme subdivision of labour in manufacturing establishments, and the exclusive attention it requires the workman to bestow on one operation, has been supposed to exert a most pernicious influence over his mental faculties. The genius of the master is said to be cultivated, but that of the workman to be condemned to perpetual neglect. Most mechanical arts, we are told, succeed best under a total suppression of sentiment and reason. A habit of moving the hand or the foot is said to be independent of either; and the workshop has been compared to an engine, the parts of which are men! (Ferguson *on Civil Society*, p. 303.) Smith, who has given so admirable an exposition of the benefits resulting from the division of labour, has notwithstanding concurred with the popular prejudices on this subject; and has gone so far as to affirm that constant application to a particular occupation in a large manufactory, " necessarily renders the workman as *stupid and ignorant as it is possible to make a human being.*" Nothing can be more marvellously incorrect than these representations. Instead of its being true that the workmen employed in manufacturing establishments are less intelligent and acute than those employed in agriculture, the fact is distinctly and completely the reverse. The weavers and other mechanics of Glasgow, Manchester, and Birmingham, possess infinitely more general and extensive information than is possessed by the agricultural labourers of any county of the empire. And this is really what a more unprejudiced inquiry into the subject would have led to anticipate. The variety of occupations in which the husbandman has successively to engage, their constant liability to be affected by so variable a power as the weather, and the perpetual change in the appearance of the objects which meet his eyes, and with which he is conversant, occupy his attention, and render him a stranger to that ennui and desire for extrinsic and adventitious excitement which must ever be felt by those who are constantly engaged in burnishing the point of a pin, and in performing the same endless routine of precisely similar operations. This want of excitement cannot, however, be so cheaply or effectually gratified in any other way as it may be by cultivating, that is, by stimulating, the mental powers. The generality of workmen have no time for dissipation; and if they had, the wages of labour in all old-settled and densely-peopled countries are too low, and the propensity to save and ac-

Different Employments of Capital and Industry.

Eulogium of Mr Malthus on manufactures.

cumulate too powerful, to permit any very large portion of them seeking to divert themselves by indulging in riot and excess. They are thus driven to seek for recreation in mental excitement; and the circumstances in which they are placed afford every possible facility for their amusing and diverting themselves in this manner. By working together, they have constant opportunities of entering into conversation; and a small contribution from each enables them to obtain a large supply of newspapers and of the cheaper class of periodical publications. But whatever difference of opinion may exist respecting the cause, there can be no doubt of the fact, that the workmen employed in manufactures have become more intelligent according as their numbers have increased, and as their employments have been more and more subdivided. We do not believe that they ever were less intelligent than the agriculturists; but, whatever may have been the case formerly, none will now venture to affirm that they are inferior to them in intellectual acquirements, or that they are mere machines without sentiment or reason. Mr Malthus, whose leanings were all on the side of agriculture, has justly observed, that "Most of the effects of manufactures and commerce on the general state of society are in the highest degree beneficial. They infuse fresh life and activity into all classes of the state, afford opportunity for the inferior orders to rise by personal merit and exertion, and stimulate the higher orders to depend for distinction upon other grounds than mere rank and riches. They excite invention; encourage science and the useful arts; spread intelligence and spirit; inspire a taste for conveniencies and comforts among the labouring classes; and, above all, give a new and happier structure to society, by increasing the proportion of the *middle classes*,—that body on which the liberty, public spirit, and good government of every country must mainly depend. (*Observations on the Effects of the Corn Laws*, p. 29.)

Rate of profit true test of the advantage of different employments.

Thus then we arrive, by a different route, at the same result we have already endeavoured to establish. The inextinguishable passion for gain—the *auri sacra fames*—will always lead capitalists to employ their stocks in those branches of industry which yield, all things considered, the highest rate of profit. And it is clear to demonstration, that employments yielding the highest profits are those in which it is most for the public interest that capital should be invested. The profits of a particular branch of industry are rarely raised except by an increased demand for its produce. Should the demand for cottons increase, there would be a greater competition for them; and as their price would, in consequence, be augmented, the manufacturers would obtain comparatively high profits. But the rate of profit in different employments has a natural tendency to equality; and it can never, when monopolies do not interpose, continue either permanently higher or lower in one than in the rest. As soon, therefore, as the rise in the price of cottons had taken place, additional capital would begin to be employed in their production. The manufacturers engaged in the cotton trade would endeavour to borrow additional capital, and the capitalists engaged in less lucrative employments would gradually contract their businesses, and transfer a portion of their stock to where it would yield them a larger return. The equilibrium of profit would thus be again restored. For the additional capital employed in the production of cottons, by proportioning their supply to the increased demand, would infallibly reduce their price to its proper level. Such is the mode in which the interests of individuals are, in every case, rendered subservient to those of the public. High profits attract capital; but high profits in particular businesses are the effect of high prices; and these are always reduced, and the commodities brought within the command of a greater number of purchasers, as soon as additional capital has been employed in their production. It is clear, therefore, that that employment is the best which yields the greatest profit; and hence, if two capitals yield equal profits, it is a proof that the departments of industry in which they are respectively invested, how much soever they may differ in many respects, are equally beneficial. Nothing can be more nugatory than to apprehend that the utmost freedom of industry should attract capital to a comparatively disadvantageous employment. If capital flow to manufactures or commerce rather than to agriculture, it is only because it has been found to yield larger profits to the individual, and consequently to the state.

Different Employments of Capital and Industry.

PART III.

DISTRIBUTION OF WEALTH.

Having thus endeavoured to trace the various methods by which that labour which is the only source of wealth may be rendered most productive, and to exhibit the relation and dependence of the different kinds of industry, we proceed to the second division of our subject, or to an investigation of the laws regulating the proportions in which the various products of art and industry are distributed among the different classes of the people.

SECT. I.—*Primary Division of the Produce of Industry.—Value of Commodities measured in the Earliest Stages of Society by the Quantities of Labour expended in their Production.*

Primary division of the produce of industry.

It is evident that only three classes—labourers, capitalists, and proprietors of land, are ever directly concerned in the production of commodities. It is to them, therefore, that all that is derived from the surface of the earth, or from its bowels, by the united application of immediate labour and of capital, must primarily belong. The other classes of society have no revenue except what they derive, either voluntarily or by compulsion, from these three classes.

But although there be no state of society in which any class besides labourers, landlords, and capitalists, participates directly in the produce of industry, there are states of society in which that produce belongs exclusively to one only of these classes; and others in which it belongs to two of them, to the exclusion of the third. The reason is, that, in the earliest stages of society, there is little or no capital accumulated, and the distinction between labourers and capitalists is, in consequence, unknown; and that, in all newly-settled and unappropriated countries, abundance of fertile land may be obtained without paying any rent.

Quantity of labour the regulating principle of value.

In that remote period which preceded the establishment of a right of property in land, and the accumulation of capital or stock—when men roamed, without any settled habitations, over the surface of the earth, and existed by means of the labour required to appropriate its spontaneous productions—the whole produce of labour would belong to the labourer, and the quantity of labour expended in procuring different articles would plainly form the only standard by which their relative worth or exchangeable value could be estimated. "If among a nation of hunters," says Dr Smith, "it usually costs twice the labour to kill a beaver that it does to kill a deer, one beaver would naturally exchange for or be worth two deer. It is natural, that what is usually the produce of two days' or two hours' labour, should be worth double of what is usually the produce of one day's or one hour's labour.

"If the one species of labour should be more severe than the other, some allowance will naturally be made for this superior hardship; and the produce of one hour's labour in

Primary Division of the Produce of Industry.

the one way, frequently exchanges for that of two hours' labour in the other.

"Or if the one species of labour requires an uncommon degree of dexterity and ingenuity, the esteem which men have for such talents will naturally give a value to their produce, superior to what would be due to the time employed about it. Such talents can seldom be acquired but in consequence of long application, and the superior value of their produce may frequently be no more than a reasonable compensation for the time and labour which must be spent in acquiring them. In the advanced state of society, allowances of this kind, for superior hardship and superior skill, are commonly made in the wages of labour; and something of the same kind must probably have taken place in the earliest and rudest period.

"In this state of things, the whole produce of labour belongs to the labourer; and the quantity of labour commonly employed in acquiring or producing any commodity, is the only circumstance which can regulate the quantity of labour (of other commodities) which it commonly ought to purchase, command, or exchange for." (*Wealth of Nations*, p. 22.)

Thus far there is no room for doubt or difference of opinion. When there are none but labourers, all the produce of labour must obviously belong to them; and the quantity of labour required to produce commodities forms the only standard by which their exchangeable worth or value can be estimated. It is at this point, therefore, that we are to begin the investigation of the laws regulating the division of the produce of industry among the three great classes of labourers, capitalists, and landlords; and we shall do this by endeavouring, in the first place, to acquire a knowledge of the laws which regulate the exchangeable value of commodities in an advanced period of society, when circulating and fixed capital are employed in their production, and when land is appropriated and rent paid. A previous acquaintance with the circumstances which determine the value of commodities will be found to be indispensable to enable us to ascertain the principles which regulate their distribution.

SECT. II.—*Preliminary Considerations.—Equality of Wages and Profits.—Inquiry into the Effect of Variations of Demand and Supply on Price.—Cost of Production shown to be its regulating Principle.*

Preliminary considerations.

If the popular opinions on this subject were well founded, the inquiry on which we are now about to enter might be disposed of in a very few words. The exchangeable value of commodities, when compared with each other, and their value or price when compared with money, is held almost universally to depend on their abundance or scarcity in the market, compared with the demand. We believe, however, that this opinion rests on no good foundation, and that the cost of production is the grand regulating principle of price. But before proceeding further, it may be proper, the better to facilitate our investigations in this and the following sections, to premise, that wherever industry is free, the rate of wages earned by the labourers engaged in any particular department, and the rate of profit derived from the capital vested in it, cannot, for any considerable period, either fall below, or rise above, the rates of wages and profits accruing to the labourers and capitalists engaged in other departments.

Equality of the wages earned by the labourers engaged in different branches of industry.

With regard to the *first* of these positions, or to the equality of the wages earned by those engaged in different employments, it is not meant to infer that all labourers receive precisely the same sum of money, or the same proportion of the produce of their labour. Such an opinion would be equally at variance with fact and with principle. Wages are a compensation made to the labourer for the exertion of his physical powers, or of his skill or ingenuity. They must, therefore, vary according to the greater intensity of the labour to be performed, and to the degree of skill and ingenuity required. Wages would not be equal if a jeweller or engraver, for example, received no higher rate than a common farm-servant or scavenger. A long course of training is required to instruct a man in the businesses of jewellery and engraving; and if this were not compensated by a higher rate of wages, none would choose to learn so difficult an art, and all persons would addict themselves, in preference, to such employments as hardly require any training. The cost of producing artificers or labourers regulates the wages they obtain, in the same way that the cost of producing commodities regulates their value. A man who practises a difficult or nice business loses all the time spent in his apprenticeship, and generally all the clothes and provisions he consumes during the same period. He should, therefore, besides receiving the same rate of wages as husbandry labourers, and those who do not require to serve an apprenticeship, receive an additional rate, proportional to the extra time and expense spent in learning his business. If he did not obtain this additional rate, it is plain he would not be so well paid as the husbandry labourers; and if he obtained more than a fair and reasonable compensation for the greater expense to which he had been put, there would be an influx of labourers into that particular business, and competition would not fail to reduce wages to their proper level.

Equality of Wages and Profits.

Besides this prominent cause of apparent inequality, wages vary in amount proportionally to the ease and hardship, the agreeableness and disagreeableness, the constancy and inconstancy, of employment. In the greater part of manufactures, a journeyman may, except in periods of general distress, usually obtain constant employment. But there are several businesses, such, for example, as those of masons and bricklayers, that can neither be carried on in hard frost nor foul weather. Their earnings should, therefore, be able not only to maintain them while they are employed, but also while they are idle, and to make them some compensation for those anxious and desponding moments which the thought of so precarious a situation must sometimes occasion. Hence, says Dr Smith, "where the computed earnings of the greater part of manufacturers are nearly upon a level with the day-wages of common labourers, those of masons and bricklayers are generally from a half more to double those wages. Where common labourers earn four and five shillings a week, masons and bricklayers frequently earn seven and eight; and where the former earn nine or ten, as in London, the latter commonly earn fifteen and eighteen." (*Wealth of Nations*, p. 47.)

But these variations, instead of being inconsistent with the principle we have been endeavouring to establish, plainly result from it. Wages are equal, not when each workman earns the same number of shillings or of pence in a given space of time; but when each is paid in proportion to the severity of the labour he has to perform, to the degree of previous education and of skill that it requires, and to the other causes of variation. So long, indeed, as the principle of competition is allowed to operate without restraint, or while every one may employ himself as he pleases, the higgling of the market will always adjust the rate of wages in different employments on the principle now mentioned, and it will, taking everything into account, be very nearly equal. If the rate of wages in one department were depressed below the common level, labourers would leave it to go to others; and were it to rise above this common level, labourers would be attracted from those departments where wages were lower, until the increased supply had sunk them to their just level. A period of greater or less duration, according to the circumstances of the country at the time, is always required to bring about this equalization. But all theoretical inquiries, and such as have the establishment of principles for their

Equality of Wages and Profits.

object, either are, or should be, founded on periods of average duration; and whenever such is the case, we may always, without occasioning the slightest error, assume that the wages earned in different employments are, all things considered, about equal.

Equality of the profits of the capital employed in different businesses.

In like manner, the profit accruing to the capitalists engaged in different businesses varies proportionally to the greater or less risk, and other circumstances specially affecting the capital they employ in them. It is obvious, indeed, that profits have not attained their level until they have been adjusted so as to balance these different advantages and disadvantages. None would engage in unusually hazardous undertakings, did the capital employed in them only yield the same profit that might be obtained by employing it in more secure businesses. No one will voluntarily place his fortune in a situation of comparative danger. Extraordinary risk must be compensated. And hence the well-known distinction between *gross* and *nett* profit. Gross profit varies according to the risk, respectability, and agreeableness of different employments, whereas nett profit is at any particular period the same, or very nearly the same, in them all. A gunpowder manufacturer, for example, must obtain as much profit, over and above that obtained from the capital engaged in the securest businesses, as will suffice to guarantee or *insure* his capital from the extraordinary risk to which it is exposed in a business of such extreme hazard. Were he to obtain *more* than this rate, additional capital would be attracted to his business, and were he to obtain *less*, capital would be withdrawn from it. The constantly-acting principle of competition, or, which is the same thing, the self-interest of every individual, will not permit the wages or profits of any particular set of workmen or capitalists, taking all things into account, to continue either long below or long above the common and average rate of wages and profits obtained by those who are employed, or have capital vested in other businesses. It is by this common standard that the wages and profits of particular businesses are always regulated; they can never diverge considerably from it; they have a constant tendency to equalization; and may, in theoretical inquiries, be supposed, without occasioning any error of consequence, exactly to coincide.

The equality, or rather the constant tendency to equality, of the wages earned by the labourers, and of the profits derived from the capital employed at the same time in the various branches of industry, was pointed out by Mr Harris, and also by Mr Cantillon in his work entitled The Analysis of Trade, &c. published in 1759; but it was first fully demonstrated in the eighth, ninth, and tenth chapters of the first book of the Wealth of Nations. The establishment of this principle was one of the greatest services rendered by Dr Smith to the science. Nothing can be more convincing and satisfactory than his reasoning on this subject. The equality of wages and of profits has, since the publication of his work, been always assumed as admitted and incontestible.

Variations of demand and supply exert no permanent influence on price.

The equality of wages and profits once established, it is easy to see that variations in the demand and supply of commodities can exert no lasting influence over price. The cost of production, denominated by Smith and the Marquis Garnier necessary or natural price, is the ultimate regulator of the value of every commodity not subject to a monopoly, and which may be indefinitely increased in quantity by the application of fresh capital and labour to its production. That the market price of such commodities and their cost do not always coincide, is certain; but they cannot, for any considerable period, be far separated, and have a constant tendency to equality. It is plain that no man will continue to produce commodities if they sell for *less* than the cost of their production; that is, for less than will repay the outlay upon them, including the ordinary rate of profit on the capital employed. This is a limit below which it is obvious prices cannot be permanently reduced; and it is equally obvious that were they, for any considerable period, to rise above it, additional capital would be attracted to the advantageous business, and the competition of the producers would lower prices.

Equality of Wages and Profits.

The will and the power to purchase necessary to constitute demand.

A demand, to be effectual, must be such as will cover the expense of production. If it be insufficient to do this, it cannot make commodities be produced and brought to market. A real demander must have the *power*, as well as the *will*, to purchase. A person with a sovereign in his pocket may be as anxious—nay, he may be ten times more anxious—to become the purchaser of a coach than of a hat; why then does he not obtain the one as readily in exchange for his sovereign as the other? The reason is obvious; a sovereign will pay the expense of producing the one, but it will not pay the expense of producing the other. Were such an improvement made in the art of coachmaking as should enable coaches to be manufactured as cheaply as hats, then a sovereign would buy a coach as easily as it can now buy a hat. The demand for any particular commodity may become ten or twenty times more extensive, or it may decline in the same proportion; but if the cost of its production continue the same, no permanent variation will be occasioned in its price. Suppose, for example, that the demand for hats were suddenly doubled: that circumstance would undoubtedly occasion a rise of price, and the hatters would, in consequence, make large profits; but this rise would only be of very limited duration; for the large profits would immediately attract additional capital to the hat manufacture; an increased supply of hats would be brought to market, and if no variation took place in the cost of production, their price would infallibly sink to its former level. Suppose, on the other hand, that the demand for hats is increased tenfold, and that the cost of their production is diminished in the same proportion: we should, notwithstanding the increased demand, be able, in a very short time, to buy a hat for the tenth part of what it now costs. Again, suppose the demand for hats to decline, and the cost of producing them to increase, the price would, notwithstanding the diminished demand, gradually rise, till it had reached the point at which it would yield the hatters the common and average rate of profit on the capital employed in their business. It is admitted that variations of demand and supply occasion temporary variations of price. But it is essential to remark, that these variations are only temporary. The cost of production is the grand regulator of price—the centre of all those transitory and evanescent oscillations on the one side and the other; and wherever industry is free, the competition of the producers will always elevate or sink prices to this level.

Cost of production the regulating principle of price.

In certain branches of industry, such, for example, as agriculture, which are liable to be seriously affected by variations of the seasons, and from which capital cannot be easily withdrawn, there is a somewhat longer interval than in others before the market price of produce and the cost of its production can be equalized. But that such an equalization will be brought about in the end is certain. No farmer, and no producer whatever, will continue to bring corn or other products to market, unless they sell for such a price as will pay the expense of their production, including therein the common and average rate of profit on the capital employed.[1] An excess of supply occasionally de-st of uction egulat- Princi- f Price.

---

[1] Some of the advocates of the agricultural interest have represented this as one of the "dangerous dogmas" of the Scotch Economists! But it can boast of a much more remote origin:—"*Nemo enim sanus*," says Varro, "*debet velle impensam ac sumptum facere in culturam, si videt non posse refici.*" (*De Re Rustica*, lib. i. § 2.)

presses the prices of corn and other farm produce below this level; and the occupiers of land are, in consequence, involved in the greatest difficulties; but such gluts do not continue. The cultivators of the worst soils are driven from their employment; a smaller supply is, in consequence, brought to market; and prices are adjusted so as to yield the customary rate of profit, and no more, to the agriculturists who continue the cultivation of the poorest soils. The interest of the cultivators will not permit prices to be permanently depressed below this level; and the interest of the public will not permit them to be permanently raised above it; for, if they were raised above it, the cultivators would gain more than the common and average rate of profit, and capital would, of course, be immediately attracted to agriculture, and would continue flowing in that direction, until the natural equilibrium of profit had been restored—that is, as will be afterwards seen, until the price of agricultural produce had fallen to such a sum as would yield the average rate of profit to the cultivators of the worst soils, or the improvers of the best. This is the point at which *average* prices continue stationary, or about which market prices oscillate, until the cost of production increase or diminish. Were any great discovery made in agriculture—such a one, for instance, as would reduce the cost of cultivation a half, the price of agricultural produce would speedily fall in the same proportion, and it would continue to sell at that reduced rate until the increase of population forced recourse to soils of a decreasing degree of fertility. Whenever this took place, prices would again rise, unless the influence of the decreasing fertility were countervailed by some new improvement. Why is the price of corn almost invariably higher in England than in France? Is it because we have a greater demand for it, or because of the greater cost of production in this country?

son y gold more uable n silver.

A pound-weight of gold is at present worth about *fifteen* pounds of silver. It cannot, however, be said that this is a consequence of the demand for gold being greater than that for silver, the reverse being the fact. Neither can it be said to be a consequence of an absolute scarcity of gold; for, those who choose to pay a sufficient price for it may obtain it in any quantity they please. The cause of this difference in the price of the two metals consists entirely in the circumstance of its costing about *fifteen* times as much to produce a pound of gold as to produce a pound of silver. That this is really the case, is plain from the admitted fact, that the producers of gold do not gain any greater profit than the producers of silver, iron, lead, or any other metal. They have no monopoly of the business. Every one may send capital to America, and become a producer of gold; and wherever this is the case, the principle of competition will always force the product to be sold at such a price as will pay the expenses of its production, and no more. Were a gold-mine discovered of equal productiveness with the silver-mines, the production of gold would immediately become the most advantageous of all businesses; an immense supply of that metal would, in consequence, be thrown upon the market, and its price would, in no very lengthened period, be reduced to the same level as silver.

son cot- s have lined in ce.

In further illustration of this principle, take the case of cottons. None can deny that the demand for them has been prodigiously augmented within the last fifty or sixty years; and yet their price, instead of increasing, as it should have done had the popular theory of demand and supply been well founded, has been constantly and rapidly diminishing. If it be said that this is a consequence of the supply of cottons having augmented in a still greater ratio than the demand, we answer that this is not enough to explain the fall of price. The supply could not have been brought to market, had not the diminution of prices, which has been constantly going on since the invention of spinning-jennies in 1767, been balanced by an equal diminution of the cost of production. It is to this principle—to the vastly increased facility of production, occasioned by the stupendous inventions and discoveries of Hargreaves, Watt, Arkwright, Crompton, and others—that the lower price and increased demand for cottons is exclusively owing. The increased facility of production has brought them within reach of all classes; and enabled the poorest individuals to clothe themselves in a dress which, at the accession of George III., was fully as expensive as silk.

Cost of Production the regulating Principle of Price.

Competition of the producers in a civilized society will always sink prices to the cost of production.

If a set of men were brought together from various countries, ignorant of each other's wants, and of the labour and expense necessary to produce the commodities which each possesses, these would be bought and sold according to the wants and fancies of the parties. In such circumstances, a pound of gold might be given for a pound of iron, and a gallon of wine for a gallon of small beer. As soon, however, as a commercial intercourse is established, and as the wants of society and the powers of production come to be well and generally known, an end is put to this method of bartering. Thousands of sellers then enter the market. But when such is the case, it is no longer possible to sell a pound of gold for a pound of iron; and why? because the producers of iron will undersell each other until they have, by their competition, reduced its price to such a sum as will suffice to pay the expense of its production. This is in every civilized society the pivot on which exchangeable value always turns. A civilized man may obtain articles from a savage, in exchange for toys or trinkets, which it cost infinitely less to produce; but if he try to obtain the same advantage over his own countrymen, a very short experience will satisfy him that they are quite as clear-sighted and attentive to their own interests as he is.

Thus, then, it appears, that no variation of demand, unaccompanied by a variation in the cost of production, has any lasting influence over price. If the cost of production be diminished, price will equally decline, though the demand should be increased to any conceivable extent. If the cost of production be increased, price will equally rise, though the demand should sink to the lowest possible limit.

Influence of monopolies.

It must always be remembered, that this reasoning applies only to those commodities on which competition is allowed to operate without restraint, and whose quantity may be indefinitely increased by the application of fresh capital and industry to their production. When a particular individual, or class of individuals, obtains the exclusive privilege of manufacturing certain species of goods, the principle of competition is suspended with respect to them, and their price must, therefore, entirely depend on the proportion in which they are brought to market compared with the demand. If monopolists supplied the market liberally, or kept it always as fully stocked as it would be were there no monopoly, the commodities produced by them would sell at their natural price, and the monopoly would have no further disadvantage than the exclusion of the public from an employment which every one should have power to carry on. In point of fact, however, the market is never fully supplied with commodities produced under a monopoly. All classes of producers endeavour to obtain the highest possible price for their commodities; and when they are protected by a monopoly, against being undersold by others, they either keep the market understocked, or supply it with inferior articles, or both. Under such circumstances, the price of the commodity, if it cannot be easily smuggled from abroad, or clandestinely produced at home, will be elevated to the highest point to which the competition of the buyers can raise it, and may, in consequence, be sold for five, ten, or twenty times the sum it would fetch were competition permitted to operate in its production. The *will* and *power* of the purchasers to offer a high price forms the only limit to the rapacity of monopolists.

Cost of Production the regulating Principle of Price.

Besides the articles produced under artificial monopolies, there is another class whose quantity cannot be increased by human industry, and whose price is not, therefore, dependent on the cost of production. Ancient statues, vases, and gems, the pictures of the great masters, some species of wines produced in limited quantities only from soils of a particular quality and exposure, and a few other articles, come under this description. As their supply cannot be increased, their price varies inversely as the demand, and is totally unaffected by anything else.

Average price always coincident with cost of production.

But with these exceptions, which, when compared to the great mass of commodities, are but few and unimportant, wherever industry is unfettered and competition allowed to operate, the *average* price of the various products of art and industry always coincides with the cost of their production. Should a fall take place in the market price of any commodity, it cannot be said whether it is really advantageous, or whether a part of the wealth of the producers be not gratuitously transferred to the consumers, until it be learned whether the cost of production has been equally diminished. If this be the case, the fall of price will not be disadvantageous to the producers, and will be permanent; but if this be not the case—if the cost of production continue the same—the fall must be injurious to the producers, and prices will, in consequence, again attain their former level. It is the same with a rise of prices. No rise can be permanent unless the cost of production be proportionally increased. If that cost have remained stationary, or have not increased in a corresponding ratio, prices will decline as soon as the ephemeral causes of enhancement have disappeared.

The extreme importance of having correct opinions respecting the regulating principle of price, and the discordant and erroneous opinions so very prevalent with regard to it, will, we hope, be deemed a sufficient apology for the length of the previous remarks, and for the insertion of the following paragraph from the *Histoire de la Monnaie* of the Marquis Garnier, in which the doctrine we have been endeavouring to establish is enforced with equal ability and eloquence.

Opinion of the Marquis Garnier.

"Mais les producteurs tendent continuellement à régler la quantité des productions sur la somme des demandes; ils ne resteront pas au-dessous de ce point, sans être tentés d'accroître la masse de leurs produits; et ils ne peuvent le dépasser sans s'exposer à perdre. Ces deux quantités, celle des produits et celle des demandes, s'efforcent donc à se mettre en équilibre l'une avec l'autre. Il existe donc un point de repos vers lequel elles gravitent chacune de son côté; un point qui est leur niveau, et c'est ce point qui constitue le *prix naturel* de la chose vénale. Quelle est la limite au-délà de laquelle le producteur ne peut porter la quantité de ses produits? C'est le prix naturel; car, s'il ne peut obtenir ce prix pour tout son produit, il sera en perte. Quelle est la borne des demandes du consommateur? C'est le prix naturel; car il ne veut pas donner plus que l'équivalent de ce qu'il reçoit. Si, par une découverte, ou par un perfectionnement de l'industrie, le producteur est mis à même d'établir l'article sur lequel il s'exerce à moins de temps et de dépense, alors le prix naturel baissera, mais aussi la somme des demandes accroîtra dans une proportion pareille, parce que plus de consommateurs seront en état de payer ce prix naturel, moins élevé que l'ancien. Le prix naturel sera toujours, pour chaque chose vénale, la limite commune au-délà de laquelle la somme des demandes de cette chose et la quantité de sa production ne devront plus faire de progrès. Quand le prix courant est le prix naturel, le producteur et le consommateur se donnent réciproquement l'équivalent de ce qu'ils reçoivent. Quand le prix courant s'écarte du prix naturel, ou c'est la consommation qui souffre au profit de la production, ou c'est la production qui souffre au profit de la consommation. Cet état de souffrance ne peut durer, et de-là procèdent les variations du prix courant. Ces variations, que Smith a expliquées et analysées avec une si parfaite lucidité, ne sont autre chose que les efforts pour revenir au prix naturel. Tenter d'expliquer ces variations, sans reconnaître l'existence d'un prix naturel, ce serait vouloir expliquer les oscillations du pendule sans convenir de sa tendance vers un centre de gravitation; ce serait supposer un effort sans but et sans mobile; ce serait admettre le mouvement et nier le repos; enfin, en voyant les phénomènes du cours des fluides et de l'équilibre des solides, ce serait contester les lois du niveau et de la pesanteur. Si les choses vénales n'ont point de prix naturel, alors les mouvements de la circulation seront dirigés par une force aveugle et inconnue; les prix moyens ne seront plus que le résultat de chances purement fortuites; il n'y aura plus d'équivalent réel; les valeurs n'auront plus de mesure naturelle; l'économie politique ne pourra plus aspirer à être au rang des sciences, puisqu'elle manquera du caractère essentiel qui les constitue telles, et que les faits dont elle traite ne seront plus fondés sur les lois immuables de la nature." (Tome i. *Introduction*, p. 62.)

Cost of Productio the regula ing Princi ple of Pric

Having thus shown that the *cost of production* is the regulating principle of price, we shall now proceed to investigate the elements which enter into and constitute this cost in an advanced state of society, when rent is paid for land, and circulating and fixed capital employed to facilitate the labour of the workman. This is, of all others, the most important, as it is the most radical inquiry in the science of the distribution of wealth; and it is indeed impossible, without possessing accurate notions on this subject, to advance a single step without falling into errors. We shall begin by endeavouring to ascertain whether rent enters into the cost of production.

SECT. III.—*Nature, Origin, and Progress of Rent.—Not a Cause, but a Consequence, of the High Value of Raw Produce.—Does not enter into Price.—Distinction between Agriculture and Manufactures.*[1]

Definition of rent.

Rent is properly "that portion of the produce of the earth which is paid by the occupier to the landlord for the use of the *natural and inherent* powers of the soil." If buildings have been erected on a farm, or if it have been enclosed, drained, or in any way improved, by an expenditure of capital and labour, the sum which a farmer will pay to the landlord for its use will be composed, not only of what is properly rent, but also of a remuneration for the use of the capital laid out on its improvement. In common language these two sums are always confounded, under the name of rent; but in an inquiry of this nature, it is necessary to consider them as perfectly distinct. The laws by which rent and profits are regulated being totally different, those which govern the one cannot be ascertained if it be not considered separately from the other.

---

[1] The theory of rent explained in this chapter was first promulgated and satisfactorily established in a tract on the Corn Laws, Edinburgh, 1777 (see p. 45–47). The author of this original and most important theory, Dr James Anderson, was a native of Hermandston in Mid-Lothian, and subsequently editor of the Bee and other publications; in one of which (Observations on Agriculture and Natural History, &c. v. pp. 401–405), he gave a new exposition of his theory. But notwithstanding the clear and able manner in which he explained his doctrines, and their ingenuity and importance, they do not appear to have attracted the least attention, and seem to have been completely forgotten. So much so was the case, that when Mr Malthus[*] and Sir Edward West[†] published tracts in 1815, explaining the nature and origin of rent, they were universally believed to be the authors of the theory. There is, we believe, no doubt as to their originality. Still, however, they were merely expositors of what had been clearly and ably explained about forty years previously to the publication of their pamphlets.

[*] An Inquiry into the Nature and Progress of Rent.

[†] Essay on the Application of Capital to Land, by a Fellow of University College, Oxford (Sir E. West).

rent on the set- g of any ntry.

On the first settling of any country abounding in large tracts of unappropriated land, no rent is ever paid; and for the obvious reason, that no person will pay rent for what may be procured in unlimited quantities for nothing. Thus, in New Holland, where there is an ample supply of unappropriated land, it is certain, that, until the best lands are cultivated, no such thing as rent will ever be heard of. Suppose, however, that tillage has been carried to this point, and that the increasing demand can, in the actual state of the science of agriculture, be no longer supplied by the best lands; it is plain, in this case, that either the increase of population must cease, or the inhabitants consent to pay such an additional price for raw produce as will enable the *second* quality of land to be cultivated. No advance short of this will procure them another bushel of corn; and competition will not, as will be immediately seen, allow them to pay more for it. They have, therefore, but one alternative. If they choose to pay a price sufficient to cover the expense of cultivating land of the second quality, they will obtain additional supplies; if they do not, they must want them. Suppose, now, that the consumers offer such a price as will pay the expense of producing corn on soils which, in return for the same expenditure as would have produced 100 quarters on lands of the *first quality*, will only yield 90 quarters; it is plain it will then be indifferent to a farmer whether he pay a rent of ten quarters for the first quality of land, or farms the second quality, which is unappropriated and open to him, without paying any rent. If the population went on increasing, lands which would yield only 80, 70, 60, 50, &c. quarters in return for the same expenditure that had obtained 100 quarters from the best lands, might be successively brought under cultivation. And when recourse had been had to these inferior lands, the rent of the higher qualities would plainly be equal to the difference, or the value of the difference, between their produce and the produce of the worst quality under cultivation. Suppose, for example, that the worst quality under cultivation yields 60 quarters, then the rent of the *first* quality will be 40 quarters, or 100 — 60; the rent of the *second* quality would, in like manner, be equal to the difference between 90 and 60, or 30 quarters; the rent of the third quality would be equal to 80 — 60, or 20 quarters, and so on. But it is material to remark, that the produce raised on the land last cultivated, or with the capital last applied to the soil, is always sold at its *necessary price*, or at that price which is just sufficient to yield the cultivators the common and average rate of profit, or, which is the same thing, to cover the cost of its production. If the price were above this level, then agriculture would be the best of all businesses, and tillage would be immediately extended; while, on the other hand, if the price fell below this level, capital would be withdrawn from the soil, and the poorer lands thrown out of cultivation. Under such circumstances, it is clear that no rent would enter into the price of the produce raised by means of the capital last applied to the soil. Its price is exclusively made up of wages and profits. The proprietors of the superior lands obtain rent; but this is the necessary result of their greater fertility. The demand cannot be supplied without cultivating inferior soils; and, to enable them to be cultivated, their produce must fetch such a price as will afford the ordinary rate of profit to their cultivators. This price will, however, yield a surplus over and above the ordinary rate of profit to the cultivators of the more fertile lands, and *this surplus is rent.*

gin of

gress of

An increase of rent is not, therefore, as is very generally supposed, occasioned by improvements in agriculture, or by an increase in the fertility of the soil. It results from the necessity of resorting, as population increases, to soils of a *decreasing* degree of fertility, and from the inability to apply capital indefinitely to the best land, without a diminished return. Rent varies in an inverse proportion to the amount of produce obtained by means of the capital and labour employed in cultivation; that is, it increases when the profits of agricultural labour diminish, and diminishes when they increase. Profits are at their maximum in countries like New Holland, Indiana, and Illinois, and generally in all situations in which no rent is paid, and the best lands only cultivated; but it cannot be said that rents have attained their maximum so long as capital yields any surplus in the shape of profit.

A quarter of wheat may be raised in the Vale of Gloucester, or the Carse of Gowrie, at perhaps a *fourth* or a *fifth* part of the expense necessary to raise it on the worst soils in cultivation. There cannot, however, be at the same time two or more prices for the same article in the same market. And it is plain, that unless the average market price of wheat be such as will indemnify the producers of the portion of the crop raised on the worst soils, they will cease bringing it to market, and the required supplies will no longer be obtained; and it is equally plain, that if the market price of wheat exceed this sum, fresh capital will be applied to its production, and competition will soon sink prices to their natural level—that is, to such a sum as will afford the common and ordinary rate of profit to the raisers of that portion of the required supply which is produced in the most unfavourable circumstances, and with the greatest expense. The cost of producing this portion will always determine the average price of all the rest. And therefore it is plainly indifferent to the consumers whether, in an advanced stage of society, the excess of return over the cost of production on lands of the first quality belong to a non-resident landlord or an occupier. It must belong to the one or the other. Corn is not high because a rent is paid, but a rent is paid because corn is high—because the demand is such that it cannot be supplied without cultivating soils of a diminished degree of fertility, as compared with the best. Suppose there is an effectual demand for ten millions of quarters, and that *one* million of them must be raised on lands which yield nothing but the common and average rate of profit to their cultivators; it is clear that the relinquishing of the rents payable by the superior lands would be no boon to the cultivators of the inferior lands. It would not lessen their expenses; that is, it would not lessen the amount of capital and labour necessary to produce the portion of the required supply raised under the most unfavourable circumstances; and, unless it reduced this expense, it is quite impossible, supposing the demand not to decline, that it should lower prices. Although, therefore, landlords were to give up the whole of their rents, their doing so would have no influence upon the price of corn. Such an act would turn farmers into landlords, and landlords into beggars; but there its effect would stop. But the case is altogether different when the cost of production varies. If it be diminished, the competition of the producers will infallibly sink prices in an equal proportion. If it be increased, no supplies will be brought to market, unless the price rise to a corresponding level. In no case, therefore, whether the demand be great or small—whether for one or a million quarters—can the price of raw produce permanently exceed or fall below the sum required to pay the cost of producing that portion of the necessary supply that is raised on the worst land, or with the last capital laid out on the soil.

Objections to this theory.

Two objections have been made to this theory. In the *first* place, it has been said that, though it may hold in a country like New Holland, where land is not appropriated, yet that the worst land in every civilized and appropriated country, like England, always yields some small rent to the proprietor; and that, therefore, it cannot be said that the price of produce is, in such countries, determined by the cost of raising it on that quality of land which pays no rent.

It has been justly observed of this objection, that even were it well founded, it would not practically affect any of the conclusions we have endeavoured to establish. There are in England and Scotland thousands upon thousands of acres of land which do not let for L.100; but to cultivate them would require an outlay of many millions, and the rent would consequently bear so small a proportion to the expenses of production, as to become altogether evanescent and inappreciable.

Land in every extensive country which yields no rent.

There can be no doubt, however, that there is in this, and most other extensive countries, a great deal of land which yields no rent. In the United States and Russia such is unquestionably the case; and yet no one presumes to say that the laws which regulate rent in these countries are different from those which regulate it in England and France. The poorest lands are always let in immense tracts. If it were attempted to let particular portions of these tracts separately, they would bring no rent; but they appear to yield rent, because rent is paid, not for them, but for the more fertile spots intermixed with them.

Payment of rent on all soils not inconsistent with the principle that rent does not enter into price.

But although it were really true that every rood of land in Britain paid a high rent, it would still be true that such rent did not, and could not, enter into the price of raw produce. The rent of a country consists of the difference, or the value of the difference, between the produce obtained from the capital first applied to the land, and that which is last applied to it. It would, as has been already seen, be exactly the same thing to the cultivator, whether he paid a rent of ten quarters for land yielding, with a certain outlay, a hundred quarters of corn, or employed the same capital in cultivating inferior land yielding only ninety quarters, for which he paid no rent. Were it possible always to obtain a hundred quarters for every equal additional capital applied to the superior soils, no person, it is obvious, would resort to those of inferior fertility. But the fact that, in the progress of society, new and less fertile land is always brought into cultivation, demonstrates that additional capital and labour cannot be indefinitely applied with the same advantage to the old land. The state of society in any particular country may be such, the demand for agricultural produce may be so great, that every quality of land actually yields rent; but it is indifferent, if there be any capital employed on land which yields only the return of stock with its ordinary profits, whether that capital be employed on old or new land. Now, that there is a very large amount of capital employed in such a manner in this and every other country, is abundantly certain. A farmer who rents a farm, besides employing on it as much capital as will, at the existing prices of raw produce, enable him to pay his rent, to obtain the average rate of profit, and to replace his stock previously to the expiration of his lease, will employ additional capital, if it will only replace itself, and afford the ordinary rate of profit. His employing this additional capital depends entirely on the price of raw produce being such as will repay his expenses and profits; for he knows he will have no additional rent to pay. Even at the expiration of his lease, his rent will not be raised; for if the landlord should require rent because an additional capital had been employed, he would withdraw it; since, by employing it in agriculture, he gets only the same profits he might get by employing it in any other department of industry. If the capital last applied to the soil yield *more* than the common and average rate of profit, fresh capital will be vested in agriculture, and competition will sink prices to a level that will enable them to yield this rate, and no more; if the capital last applied to the soil yield *less* than this common and average rate of profit, it will be withdrawn, until, by the rise of price, the last remaining capital yields this common rate. In every case, therefore, whether the last quality of land taken into cultivation yields rent or not, the last capital applied to the soil yields only the common and average rate of profit; and, consequently, the price of the produce which it yields, and which regulates the price of all the rest, is totally unaffected by rent.

Does not suppose that landlords will allow farmers to occupy their lands without paying rent.

It has, in the *second* place, been objected to this account of the nature and causes of rent, that it takes for granted, that, in all extensive countries, landlords permit the farmers of the worst lands to occupy them without paying any rent. But it is easy to see that this is a mistake. The price of raw produce is kept down to its necessary price by the competition of farmers, and not by that of landlords. Though there must necessarily be a very wide difference, in any country of considerable extent, between the best and worst soils, the gradation from the one extreme to the other is gradual, and almost imperceptible. The best differ but little from those immediately inferior to them, and the worst from those immediately above them. And hence it is quite as impossible to point out the precise point where the first quality ends and the second begins, or where the second ends and the third begins, as it is to point out the precise point where the contiguous colours of the rainbow differ. Now, suppose that the numbers 1, 2, 3, 4, 5, 6, 7, &c. designate the different qualities of soil in an extensive country, and suppose that the effectual demand for raw produce is such as will afford the common and average rate of profit to those who cultivate land of the *fifth* degree of fertility, or that represented by No. 5; when such is the case, there can be no doubt that No. 5 will be cultivated; for, besides the peculiar attractions which agriculture possesses, it would be quite as advantageous to cultivate it as to engage in any other business. It would not, however, be more advantageous; for its produce would yield no surplus in the shape of rent. But suppose that a combination took place among the proprietors of Nos. 1, 2, 3, 4, and 5, to withhold a portion of their produce from market; and that, in consequence of this or any other cause, the price of corn is raised a little above the expense of its production on No. 5; in that case it is obvious that soils of the *very next* degree of fertility, or that that portion of No. 6 which, in point of productive power, differs extremely little from No. 5, would be brought under cultivation; and the increased supply would infallibly sink prices to the level that would afford the average rate of profit, and no more, to the cultivators of No. 5, or of the poorest soils which the supply of the effectual demand renders it necessary to cultivate. It is quite the same, therefore, in so far as price is concerned, whether a country be appropriated or not. When it is appropriated, prices are kept down to their lowest limit by the competition of the landlords. And it is by the same principle—the cost of producing that portion of the necessary supply raised under the most unfavourable circumstances—that the price of raw produce is determined in England and France, and in New Holland and Illinois.

Does not account both for a rise and fall of price in the same way.

But then it is said that this reasoning involves a contradiction; that it accounts for a rise and a fall of price in the same way, or by an extension of cultivation! In point of fact, however, it does no such thing. The market price of corn will always be low where it is cheaply produced, as in Poland; and it will occasionally be low where it costs a great deal to produce it, when a redundant supply is brought to market. Suppose, as before, that the effectual demand for corn in Great Britain is such as will enable lands of the *fifth* degree of fertility to be cultivated; but that, owing to variable harvests, to injudicious encouragement held out by the legislature, the ardour of speculation, the miscalculation of farmers, or any other cause, lands of the *sixth* degree of fertility have been cultivated; the increased quantity of produce that must thus be thrown on the market will plainly depress prices to such an extent that, instead of yielding average profits to the cultivators of No. 6, they will not yield them to the cultivators of No. 5. But they will yield *more* to them than to the cultivators of No. 6. The latter, therefore, will be first driven from their business; and when they have retired, prices will rise, not indeed to such a height as to enable No. 6 to be cultivated, but so high as to enable the cultivators of No. 5 to continue their business; that is, as has been already shown, to such a sum as will enable the raisers of the last portion of the necessary supply to obtain the common and average rate of profit. Should the demand, instead of continuing stationary, increase so that it could not be supplied without cultivating Nos. 6 and 7, the price will rise in proportion to the increased expense of their cultivation. But to whatever extent the demand might increase, still, were such an improvement made in agriculture, or in the art of raising corn, as would enable the supply to be obtained from No. 1 only, the price would infallibly fall to the sum that paid the expenses of its cultivators, and rent would entirely disappear.

stinction ween riculture d manu- tures d com- rce.

This analysis of the nature and causes of rent discovers a fundamental distinction between agricultural and commercial and manufacturing industry. In manufactures, the worst machinery is first set in motion, and its powers are progressively improved by new inventions; and it is rendered capable of yielding a greater amount of produce with the same expense. And as no limits can be assigned to the quantity of improved machinery that may be introduced; as a million of steam-engines may be constructed for the same, or rather for a less, proportional expense than would be required for the construction of one; the competition of capitalists never fails to reduce the price of manufactured commodities to the sum which the least expensive method of production necessarily requires for their production.

ndency nanufac- red pro- ts to fall price.

ndency agricul- al pro- cts to e in price.

In agriculture, on the contrary, the best machinery, that is, the *best soils*, are first brought under cultivation, and recourse is afterwards had to inferior soils, requiring a greater expenditure of capital and labour to produce the same supplies. The improvements in the construction of farming implements, and meliorations in agricultural management, which occasionally occur in the progress of society, countervail to a greater or less extent the decreasing fertility of the soil. But the fall of price, which is permanent in manufactures, is only temporary in agriculture. A fall in the price of raw produce, by enabling every class to obtain greater quantities than before for their products or their labour, raises the rate of profit, and leads, of course, to an increased accumulation of capital; and this necessarily leads to a greater demand for labour, to higher wages, to an increased population, and, consequently, to a further demand for raw produce and an extended cultivation. Agricultural improvements check for a while the necessity of having recourse to inferior soils and the rise of rents; but the check cannot be lasting. The stimulus which they at the same time give to improvement and population is sure in the end to raise prices, and, by forcing recourse to poor lands, to raise rents.

rth com- red by althus to series of chines dowed th differ- t pro- ctive wers.

Malthus, in illustrating this important distinction between agricultural and manufacturing industry, set the doctrine of rent in a striking point of view. "The earth," he observes, "has been sometimes compared to a vast machine, presented by nature to man for the production of food and raw materials; but, to make the resemblance more just, as far as they admit of comparison, we should consider the soil as a present to man of a great number of machines, all susceptible of continued improvement by the application of capital to them, but yet of very different original qualities and powers.

"This great inequality in the powers of the machinery employed in procuring raw produce, forms one of the most remarkable features which distinguishes the machinery of the land from the machinery employed in manufactures.

"When a machine in manufactures is invented which will produce more finished work with less labour and capital than before, if there be no patent, or as soon as the patent is over, a sufficient number of such machines may be made to supply the whole demand, and to supersede entirely the use of all the old machinery. The natural consequence is, that the price is reduced to the price of production from the best machinery; and if the price were to be depressed lower, the whole of the commodity would be withdrawn from the market.

"The machines which produce corn and raw materials, on the contrary, are the gifts of nature, not the works of man; and we find by experience that these gifts have very different qualities and powers. The most fertile lands of a country, those which, like the best machinery in manufactures, yield the greatest products with the least labour and capital, are never found sufficient to supply the effective demand of an increasing population. The price of raw produce, therefore, naturally rises till it becomes sufficiently high to pay the cost of raising it with inferior machines, and by a more expensive process; and as there cannot be two prices for corn of the same quality, all the other machines, the working of which requires less capital compared with the produce, must *yield rents in proportion to their goodness.*

"Every extensive country may thus be considered as possessing a gradation of machines for the production of corn and raw materials, including in this gradation not only all the various qualities of poor land, of which every large territory has generally an abundance, but the inferior machinery which may be said to be employed when good land is further and further forced for additional produce. As the price of raw produce continues to rise, these inferior machines are successively called into action; and as the price of raw produce continues to fall, they are successively thrown out of action. The illustration here used serves to show at once the necessity of the actual price of corn to the actual produce, and the different effect which would attend a great reduction in the price of any particular manufacture, and a great reduction in the price of raw produce.

"I have no hesitation, then, in affirming, that the reason why the real price of corn is higher and continually rising in countries which are already rich, and still advancing in prosperity and population, is to be found in the necessity of resorting constantly to poorer land,—to machines which require a greater expenditure to work them,—and which consequently occasion each fresh addition to the raw produce of the country to be purchased at a greater cost;—in short, it is to be found in the important truth, that corn is sold at the price necessary to yield the actual supply; and that, as the production of this supply becomes more and more difficult, the price rises in proportion.

"I hope to be excused for having dwelt so long, and presented to the reader in various forms, the doctrine that corn, in reference to the *quantity actually produced*, is sold at its necessary price, like manufactures, because I consider it as a truth of the highest importance, which has been entirely overlooked by the economists, by Dr Smith, and all those writers who have represented raw produce as selling always at a monopoly price." (*Inquiry into the Nature and Progress of Rent*, p. 37.)

It appears, therefore, that in the earliest stages of society, and when only the best lands are cultivated, no rent is paid. The landlords, as such, do not begin to share in the produce of the soil until it becomes necessary to cultivate lands of an inferior degree of fertility, or to apply capital to the superior lands with a diminished return. Whenever this

Nature and Causes of Rent.

is the case, rent begins to be paid; and it continues to increase according as cultivation is extended over poorer soils, and diminishes according as they are thrown out of cultivation. Rent, therefore, depends exclusively on the extension of tillage. It is high where tillage is widely extended over inferior lands, and low where it is confined to the superior descriptions only. But in no case does rent enter into price; for the produce raised on the poorest lands, or with the capital last applied to the soil, determines the price of all the rest; and this produce yields no surplus above the common and average rate of profit.

It being thus established that the circumstance of land being appropriated, and rent paid to the landlords, does not affect the price of commodities, or the principle which regulates their exchangeable value in the earliest stages of society, we have, in the next place, to inquire into the effects of the accumulation and employment of capital, and of the rise and fall of wages on the value of commodities.

SECT. IV.—*Influence of the Accumulation and Employment of Capital, and of Fluctuations in the Rate of Wages on Exchangeable Value.*

Value of commodities regulated by the amount of immediate labour and capital expended in their production.

It will be remembered, that the quantity of labour required to produce commodities, and bring them to market, formed, in the earliest stages of society, and before capital was accumulated, the standard by which their exchangeable value was regulated. But capital is merely the accumulated produce of *anterior labour;* and when it is employed in the production of commodities, their value is determined, not by the quantity of immediate labour only, but by the total quantity of immediate labour and of accumulated labour, or capital, necessarily laid out on them. Suppose that an individual can by a day's labour, without the assistance of capital, kill a deer; but that it requires a day's labour to construct the weapons necessary to enable him to kill a beaver, and another day's labour to kill it; it is evident, supposing the weapons to have been rendered useless in killing the beaver, that it took as much labour to kill the latter as was required to kill two deer, and the beaver must, therefore, be worth the two deer. The durability of the weapons, or capital of the beaver hunter, is obviously an element of the greatest importance in estimating the value of the animals he has killed. Had the weapons been more durable than has been supposed,—had they served, for example, to kill twenty beavers instead of one, then it is plain the quantity of labour required to kill a beaver would only have been one twentieth part, or five per cent., more than that required to kill a deer, and the animals would, of course, have been exchanged in that proportion. With every extension of the duration of the weapons, the value of the deer and the beaver would obviously be brought still nearer to equality.

It appears, therefore, inasmuch as capital is nothing but the produce of anterior labour, that its accumulation and employment cannot affect the principle which makes the value of commodities depend on the quantities of labour required for their production. A commodity may be altogether produced by capital, without the co-operation of any immediate labour; and if so, its value will be determined by the quantity of capital, that is, of antecedent labour, expended in its production: or it may be partly produced by capital, and partly by immediate labour, and then its value will be proportioned to the sum of the two, or, which is the same thing, to the total quantity of labour bestowed upon it. The principles now laid down are almost self-evident, and we are not aware that they have been disputed by any economist of consideration; but a considerable difference of opinion is entertained respecting the influence on value of the employment of workmen by capitalists, and of fluctuations in the rate of wages.

Exchangeable Value.

The employment of workmen by capitalists does not raise the price of commodities.

It does not, however, seem that there is much room for these differences. Suppose that a certain quantity of goods, twenty pairs of stockings, for example, manufactured by independent workmen, freely exchange for forty pairs of gloves also manufactured by independent workmen; they would necessarily continue to do so, provided the quantity of labour formerly required for their production continued invariable, though the workmen were employed by some master manufacturer. In the first case, it is true, as Dr Smith has observed, that the whole goods produced by the workmen belonged to themselves, and that, in the second case, they had to share them with others. But it must be recollected, that in the first case the capital made use of in the production of the commodities also belonged to the workmen, and that in the latter case it has been furnished them by others. The question then comes to be,—does the circumstance of labourers voluntarily agreeing to give a portion of the commodities produced by them, as an *equivalent* or compensation for the wages, that is, for the capital furnished them by others, afford any ground for raising the value of commodities? It is evident it cannot. The profits of stock are only another name for the wages of accumulated labour. They make a part of the price of every commodity in whose production any portion of capital has been wasted. But whether the capital belong to the labourer, or is supplied to him by another, is obviously of no consequence. When the capital does not belong to the labourer, the commodities he produces are divided into *two* specific portions, whereof one is the return for the immediate labour, and the other for the capital, or accumulated labour, expended on their production. But the value of the commodities is the same, into how many portions soever they may be divided. A shoemaker who manufactures shoes on his own account, must obtain the same rate of profit on their sale, that would accrue to a master-shoemaker were he employed by him as a workman. He must possess a capital adequate to maintain himself and his family until his shoes are disposed of, and he must also be able to provide himself with a workshop and tools, to advance money to the tanner to pay his leather, and to provide for various other outgoings. If he did not, exclusive of the ordinary wages of labour, realize a rate of profit, or a return for his capital, equal to the profit obtained by the master-shoemaker, it would obviously be for his advantage to lend his capital to the latter, and to work on his account; and it is plain, inasmuch as his shoes could not be sold for a higher price than those of the capitalist, that he could not realize a greater rate of profit.

It appears, therefore, that the circumstance of the accumulated labour or capital, and the immediate labour required to produce commodities, being furnished by different classes of people, makes no difference whatever on the principle which shows that their value depends on the total quantity of labour necessary for their production. It now only remains to trace the influence of fluctuations in the rate of wages on price. When this is done, the subject will be exhausted.

Effect of fluctuations in the rate of wages on exchangeable value:—

To simplify this inquiry, we shall divide it into two branches. We shall inquire, *first*, whether fluctuations in the rate of wages have any, and, if any, what effects, on the value of commodities produced by the aid of capitals of equal degrees of durability; and, *second*, whether these fluctuations have any, and, if any, what effects, when the capitals employed are of unequal degrees of durability.

I. When all classes of producers employ fixed or circulating capitals, of precisely the same degree of durability, they must be all equally affected by a rise or fall of wages. This is a principle assented to by every one, and is indeed self-evident. But when such is the case, it is plainly impossible that a rise or fall of wages should occasion any variation in the value of commodities. To revert to our *t*, Effect f these uctua-ons when e capitals mployed produc-on are of e *same* egree of rability.

former example, let it be supposed that wages, at the rate of a shilling a day, were paid by the stocking manufacturer, one pair of whose stockings exchanged for two pairs of gloves, and that, from some cause or other, the wages of his work-people have been doubled, or raised to two shillings; the question is, will he now obtain a greater quantity of gloves in exchange for his stockings? It is obvious he will not. He cannot urge the fact of his having to pay a greater amount of wages to his workmen, as a reason why the glove manufacturer should give him more gloves in exchange for his stockings; for the latter would have it in his power to reply, that the same rise of wages affected him to precisely the same extent! If, therefore, one pair of stockings were previously worth two pairs of gloves, they would continue to preserve this relation to each other, so long as the quantities of labour required for their production were not varied, whatever might be the fluctuation of wages—whether they fell to a sixpence, or rose to five shillings, a day. Even if the price of commodities rose, which it could not, when wages rose, that would be of no advantage to the producers. Commodities are always bought by commodities, or by labour. Of what consequence, then, would it be to a capitalist, when wages rose, to sell his commodities at an equal advance; when he, in his turn, would be obliged to give so much more for every article which he purchased? Were wages to rise fifty per cent. a producer, a farmer, for example, would be precisely in the same condition, whether he sold his corn for fifty per cent. advance, and gave an additional fifty per cent., as he would be obliged to do, for his hats, shoes, clothes, &c. &c. or sold his corn at its former price, and bought all the commodities which he consumes at the prices he had formerly paid for them.

In order farther to illustrate this principle, we may be allowed to make a supposition, which, although it can never actually take place, will serve to set this doctrine in a clearer point of view. Should the quantities of labour required for the production of every species of commodities be increased in exactly the same proportion, it is plain their exchangeable values would remain unaltered. Their cost would, however, be augmented. A bushel of corn would not then exchange for a greater quantity of muslins or of broad cloth than it did before the increased expense of its production; but each would be the produce of more than the former quantity of labour. Under such circumstances, the prices of commodities would remain stationary, while the wealth and comforts of the society would be materially diminished. Every person would have to make greater exertions to obtain a given quantity of any one commodity; but as the expense of producing *all* commodities is, by the supposition, equally increased, it would not be necessary to make any greater exertions to obtain one than another, and their values, as compared with each other, would be totally unaffected.

In this statement it is taken for granted that the value of money has been all the while invariable, that is, that the same quantity of labour continues necessary to produce the same quantity of money. If the value of money fluctuate,—if it become either more or less difficult of production,—then, undoubtedly, both the rate of wages and the price of commodities will vary. But they will do so, not because the labourer gets a greater or less amount of wages, but because the value of the commodity, or standard in which wages and prices are estimated, has varied. Wages, though most commonly paid in money, really consist of a portion of the produce of the industry of the labourer; consequently, they bear a high proportional, or cost value, when the labourer gets a comparatively large share of the produce of his industry, and a low proportional value when he gets a comparatively small share of that produce. Instead of being identical with wages estimated in money or commodities, proportional wages are often lowest when money wages are highest, and they are often rising at the moment that money wages are falling, and *vice versa*. And hence, in order to avoid falling into endless mistakes, it is best, in all theoretical investigations with respect to value, to consider wages in the light of a certain proportion of the produce of industry; as being really invariable, so long as this proportion continues unchanged; and as having really risen when it is increased, and really fallen when it is diminished.

The mistaking of fluctuations in the rate of money wages for fluctuations in the rate of proportional wages, has been the source of much error and misapprehension. A man whose wages are one shilling a day, must get two shillings to keep them at the same level, should the value of money decline a half; and the hat which now sells for ten shillings must then, for the same reason, sell for twenty shillings. It is obviously false to call this a real rise, either of wages or prices: this, however, is what is generally done. The manufacturer who gives sixpence a day more to his men, and who sells his goods at a proportionally higher price because of a fall in the real value of money, rarely suspects that there has been any such fall, and almost invariably concludes that the rise of wages has been the cause of the rise of prices, overlooking entirely the real cause of the rise of both—the decline in the value of the money or commodity in which wages and prices are estimated.

It has been seen that a general and equal increase of the labour required for the production of commodities cannot alter their relation to one another; and it is consequently obvious that this relation cannot be altered by a general and equal increase of the wages paid for that labour. Fluctuations in the rate of wages affect the proportion in which the produce of industry, under deduction of rent, is divided between capitalists and labourers—diminishing the proportion belonging to the capitalists when they rise, and increasing it when they fall. But as these changes in the distribution of commodities neither add to nor take from the quantity of labour required to produce them and bring them to market, they do not affect either their real or exchangeable value.

2*d*, Effect of these fluctuations when the capitals employed in production are of *different* degrees of durability.

II. We have seen by the investigation under the preceding head, that, where the capitals employed in production are of *equal* degrees of durability, fluctuations in the rate of wages affect all classes of producers to the same extent, and have, therefore, no influence on the value of commodities, or on their price. But when the capitals employed are of *different* degrees of durability, this is not the case. Fluctuations in the rate of wages do not, in such cases, equally affect all classes of producers, and the natural equilibrium of profit cannot be maintained without a variation in the value of their products. To illustrate this, let it be supposed that a certain quantity of goods, the produce of fixed capital or machinery fitted to last many years, freely exchanges for a certain quantity of other goods entirely produced by manual labour. It is plain they would not be exchanged on this footing after a rise or fall of wages: for the proprietor of the machinery would be very little affected by such fluctuations, whereas they would very seriously affect the proprietor of the goods produced by manual labour. And, therefore, when wages fluctuate, the values of the goods produced by capitals of different degrees of durability must also fluctuate—that is, they must be adjusted so that they may continue to yield the same common and average rate of profit. Let us endeavour to trace the mode in which this adjustment is effected.

The arguments now brought forward, to show the impossibility of fluctuations in the rate of wages affecting the value of commodities produced by capitals of the same durability, were first advanced by Mr Ricardo. He, too, was the first who endeavoured to analyse and discover the influence of fluctuations in the rate of wages on commodities, when the capitals employed in their production were *not* of the same degree of durability. The results of his researches in this more difficult branch of the science were still more important, and more at variance with the previously received opinions of political economists. Mr Ricardo not only showed that it was impossible for any rise of wages to raise the price of *all* commodities; but he also showed, that in many cases a rise of wages necessarily led to a *fall* of prices, and a fall of wages to a *rise* of prices! The novelty of these opinions, and the talent and ingenuity with which they were supported, immediately recommended them to general notice; and the repeated examinations to which they have been subjected have confirmed their truth, and set them in a still clearer point of view.

If a rise of wages lowers profits, it must lower the value of goods chiefly produced by fixed capital or machinery.

Suppose a manufacturer has a machine worth L.20,000, of a high degree of durability, and which can, without the assistance of any, or with but little, manual labour, produce commodities: If profits were at ten per cent., the commodities annually produced by this machine would sell for L.2000, together with a small addition to replace its wear and tear.[1] Now, it is quite clear, that if, from any cause whatever, profits either rise or fall, the price of the goods produced by this machine would also rise or fall. If profits were to rise to fifteen per cent., the price of the goods produced by the machine must, in order that its owner may obtain the same profit with other capitalists, rise to L.3000; and if, on the other hand, profits fall to five per cent., the price of his goods must, for the same reason, fall to L.1000. If, therefore, it can be shown that a rise of wages reduces the rate of profits, it is plain it must also reduce the price of such commodities as are chiefly produced by machinery, or fixed capital of a considerable degree of durability, or by circulating capital returnable at distant periods, and *vice versa*. But it is not difficult to see that this is really the case, and that, in point of fact, profits, supposing other things to continue the same, fall when wages rise, and rise when wages fall.

It is plain, from what has been previously stated, that to whatever extent wages might rise, it would be impossible for any class of producers, whether their capitals were returnable in a day, a week, or any other period, to obtain a larger share of the commodities produced by others of the *same class*,—that is, whose capitals were returnable in *equal periods* with their own. Suppose wages rise ten or twenty per cent., that would not enable the holder of a capital returnable every month, or every twelve months, to obtain any additional value in exchange for his commodities from such of his fellow-capitalists as were affected to the same extent with himself by the rise of wages,—that is, whose capitals were returnable in the same period as his own. This is as impossible as it is to change the relation of proportional numbers by multiplying or dividing them by the same number; and, therefore, it cannot be true that a rise of wages will raise the price of any one commodity, as compared with all other commodities.

But if a rise of wages cannot do this, it is demonstrably certain it must lower profits. Suppose that the numbers 1, 2, 3, 4, 5, 6, 7, 8, 9, and 10, represent capitals of corresponding degrees of durability: When wages fluctuate, the proprietors of the least durable capitals, numbers 1, 2, 3, 4, and 5, are plainly more affected thereby than the proprietors of the more durable capitals, numbers 6, 7, 8, 9, and 10. Suppose, now, that wages rise, and let us endeavour to discover what would be the effect of this rise on the holder of a capital of the *tenth* degree of durability. It has been already seen that, whatever might be the amount of the rise—whether it were one, ten, or a hundred per cent.—the holder of such capital could not obtain any additional quantity of the commodities belonging to other producers whose capitals were also of the *tenth* degree of durability; and in so far, therefore, as this class of commodities is concerned, profits will be reduced to the precise extent that wages have risen. But the holders of the other capitals are all of them *more* affected by the rise of wages than the holders of No. 10; and if we took any one of them as a standard by which to measure profits, they would appear to have fallen in a still greater proportion.

Profits vary inversely as wages.

Hence it is plain, that while other things remain the same, profits vary inversely as wages; that is, they fall when wages rise, and rise when wages fall. But, owing to the different and ever-varying proportions in which fixed and circulating capital and immediate labour are employed in the production of commodities, it is extremely difficult to discover the precise extent to which any given fluctuation in the rate of wages affects profits. We shall, however, state three different cases, which will briefly, and, it is hoped, satisfactorily, elucidate the manner in which fluctuations in the rate of wages always operate, and the method to be followed in estimating their influence on profits.

Method of estimating the effects of fluctuations in the rate of wages on profits.

1. If all commodities were produced by immediate labour, or by capital employed in the payment of wages, it is obvious that every rise of wages would cause an equal fall of profits. A capitalist who employed L.1000 in the payment of wages must, if profits were at ten per cent., sell the commodities for L.1100. But when wages rise five per cent., or to L.1050, he would not be able to sell his commodities for more than L.1100; for money is itself a commodity, and as, by the supposition, all commodities are produced by immediate labour, the rise of wages would affect the producers of money in the same degree that it affects other producers. In this case, therefore, it is plain every rise of wages will equally sink profits, and every fall of wages will equally raise them.

2. If all commodities were produced, *one half* by immediate labour, and the *other half* by capital, profits would only fall to half the extent that wages rose. Suppose a capitalist employs L.500 in the payment of wages, and L.500 as a fixed capital, when profits are at ten per cent., the commodities produced must, as before, sell for L.1100. If wages rose five per cent., the capitalist would have to pay L.525 as wages, and would, consequently, only retain L.75 as profits. In this case, therefore, a rise of wages to the extent of five per cent. would, because of the employment of equal quantities of capital and immediate labour in the production of commodities, only sink profits two and a half per cent.

3. If *all* commodities were produced by capital of a high degree of durability, the capitalists, it is obvious, would not be at all affected by a rise of wages, and profits would, of course, continue as before.

Now, suppose that commodities, instead of being wholly produced by immediate labour, as in the first case, or wholly by equal quantities of immediate labour and of capital, as in the second, or wholly by fixed capital, as in the third, are partly produced in the one mode and partly in the other, and let us see what effect this increase of five per cent. in the rate of wages would have on their relative values. To facilitate this inquiry, we shall distinguish these three descriptions of commodities by the Nos. 1, 2, and 3. Now, it is quite evident that the rise of wages has affected No. 1 two and a half per cent. more than it has affected No. 2, and five per cent. more than it has affected No. 3. No. 1

---

[1] So small a sum as two shillings and elevenpence would be sufficient for this purpose, if the machine would last for 100 years; for an annuity of two shillings and elevenpence, accumulating for 100 years at ten per cent., would at the end of that period amount to L.20,000.

must, therefore, as compared with No. 2, have risen two and a half per cent. in value, and, as compared with No. 3, it must have risen five per cent.; No. 2 must have fallen two and a half per cent. as compared with No. 1, and risen two and a half per cent. as compared with No. 3; and No. 3 must have fallen five per cent. as compared with No. 1, and two and a half per cent. as compared with No. 2. If wages, instead of rising, had fallen, the same effects would obviously have been produced, but in a reversed order. The proprietors of the commodities of the class No. 1 would gain five per cent. by the fall, those of No. 2 would gain two and a half per cent., and those of No. 3 nothing; and the relative values of their commodities would be adjusted accordingly.[1]

neral
e on the
oject of
fluctua-
ns.

Thus, then, it appears, inasmuch as any commodity taken for a standard by which to estimate the values of other commodities, must itself be produced by capital returnable in a certain period, that when wages rise, commodities produced by less durable capitals than those which produce the commodity taken for a standard, will rise in exchangeable value, and those produced by more durable capitals will fall; and conversely when wages are reduced. Suppose, as before, that the Nos. 1, 2, 3, 4, 5, 6, 7, 8, 9, and 10, represent capitals of corresponding degrees of durability: If a commodity produced by the least durable capital, No. 1, and which may be supposed to be wholly employed in the payment of wages, be taken for a standard, all commodities whatever produced by the other and more durable capitals would fall in value when wages rose; and if we suppose those produced by No. 2 to decline one per cent., those produced by No. 3 would decline two per cent., those produced by No. 4, three per cent., and so on until we arrive at No. 10, which will have fallen nine per cent. If, on the other hand, a commodity produced by the most durable capital, No. 10, and which may be supposed to consist wholly of highly durable machinery, be made the standard, when wages rise, all the commodities produced by the other less durable capitals would also rise; and if those produced by No. 9 rose one per cent., those produced by No. 8 would rise two per cent., and those produced by No. 1, nine per cent. If a commodity produced by capital of a medium degree of durability, as No. 5, and which may be supposed to consist half of circulating capital employed in the payment of wages, and half of fixed capital or machinery, be taken as a standard, the commodities produced by the less durable capitals, Nos. 4, 3, 2, and 1, will rise with a rise of wages, on the former hypothesis, the first, or No. 4, one per cent., the second, or No. 3, two per cent., &c.; while those produced by the more durable capitals, Nos. 6, 7, 8, 9, and 10, will fall, the first, or No. 6, one per cent., the second, or No. 7, two per cent., &c. exactly the reverse of the other.

Hence it is obvious that the influence which variations in the rate of wages have on price will principally depend on the nature of the capital employed in the production of gold and silver. Whatever may be the proportions of circulating and fixed capital employed in the production of money, all commodities produced by the agency of a greater quantity of labour, and with less fixed capital and machinery, will rise when wages rise, and fall when wages fall; but those that are produced by the agency of a less quantity of labour, and with more fixed capital or machinery, will fall when wages rise, and rise when wages fall; and those that are produced in nearly the same circumstances, or by the agency of the same quantities of circulating and fixed capital as money, will not be affected by fluctuation of wages.

Variations of exchangeable value caused by fluctuations in the rate of wages confined within narrow limits.

It should be observed, however, that variations in the exchangeable value of most commodities, caused by variations in the rate of proportional wages, are confined within comparatively narrow limits. It has been already seen, that were all commodities produced wholly by immediate labour, or wholly by capital, or wholly by equal quantities of both, no variation in the rate of wages would have any influence on their value. But, in point of fact, a very large class of commodities are produced by means of nearly equal portions of fixed and circulating capital; and as every rise of proportional wages that may take place must, under such circumstances, be balanced by a fall in the rate of profit, or by a proportional increase in the productiveness of industry, it is evident that the value of the commodities in question, as compared with each other, would remain nearly stationary. Although, therefore, a rise of wages has a necessary tendency to raise the exchangeable value of one class of commodities, and consequently to lower that of another, the fall of profits, which must inevitably follow every rise of wages that is not accompanied by an increased productiveness of industry, has a contrary effect, and tends to sink the value of the commodities which the increased rate of wages would raise, and to elevate the value of those which the same increased rate would sink. And it is only in extreme cases, or in the case of commodities produced almost wholly by direct manual labour on the one hand, or in that of those produced almost wholly by the aid of fixed capital or machinery on the other, that a variation in the rate of proportional wages occasions a considerable variation in their relative values.

It must also be observed, that though fluctuations in the rate of wages occasion some variation in the exchangeable value of particular commodities, they neither add to nor take from the total value of the entire mass. If they increase the value of those produced by the least durable capitals, they equally diminish the value of those produced by the more durable capitals. Their aggregate value continues, therefore, always the same. And though it may not be strictly true of a particular commodity, that its exchangeable value is directly as its cost or real value, or as the quantity of labour required to produce it and bring it to market, it is most true to affirm this of the mass of commodities taken together.

In thus endeavouring to trace the cost of all descriptions of non-monopolized commodities to the quantity of labour required for their production, it is not meant to deny that a very large portion of the useful or desirable qualities of such commodities may be the result of the action or labour of natural agents. But it is, as was previously seen, the peculiar and distinguishing feature of natural agents or powers, that they render their services gratuitously. Whatever they do is done without fee or reward. And hence, though their co-operation be necessary to the production of every species of useful and desirable articles, they add nothing to their value. This is a quality that can be communicated only by the labour of man, or by the instrumentality of capital appropriated or accumulated by his labour. In estimating the value of a quantity of corn, for example, we include only the labour of the individuals employed, as ploughmen, reapers, thrashers, &c. the value of the corn used as seed, and the value of the services rendered by the horses and instruments made use of in the different operations. Nothing whatever is set down to account of the aid derived from the vegetative powers of nature, and the action of the sun and showers; for though without them the crop could not be obtained, and our utmost exertions would be altogether fruitless, yet, as they are the free gift of Providence, they add nothing to the value of the produce, that is, they add nothing to its power of exchanging for or buying labour, or other things procured by the intervention of labour.

---

[1] These examples are substantially the same with those given by Mr Mill. See *Elements of Political Economy*, p. 77.

It may be thought, perhaps, that this principle is at variance with what is observed to take place in the production of certain descriptions of commodities. Thus, if a cask of new wine be kept for a definite period, or till it arrive at maturity, it will acquire a higher value: now, as the change produced on the wine is entirely brought about by the operation of natural agents, and as, without the change, the wine would have no higher value, it has been contended that this is a case in which the labour of natural agents is plainly productive of an increased value. But it is easy to see that this is a mistake. The cask of wine is a capital, or is the result of the labour employed in cultivating, gathering, pressing, and otherwise preparing the grapes from which it was made. But it is necessary, in order to give time for the processes of fermentation, decomposition, &c. to effect the desired changes in the wine, that it should be laid aside until they are completed. The producer of wine would not, however, employ his capital in this way, unless it were to yield the same return that is derived from capital employed in other businesses. And hence it follows, that though the processes carried on by nature render the wine more desirable, or bestow on it a greater degree of utility, they add nothing to its value; the additional value which it acquires being a consequence of the profit accruing on the capital required to enable the processes to be carried on.

Besides the objection now stated, it has been contended by Colonel Torrens, in his valuable work on the Production of Wealth, in opposition to the theory we have been endeavouring to establish, that, after capital has been accumulated, the value of commodities is no longer, as in the early stages of society, determined by the total quantities of labour required to bring them to market, but by the quantities of capital required for that purpose. At bottom, however, this theory is identical with that now explained. Capital is the accumulated produce of anterior labour; and its value, like that of everything else, is estimated by the quantity of labour required to procure it. In this respect, too, there is no difference, as has been already seen, between labourers and any other species of machines. A labourer is himself a portion of the national capital, and may, without impropriety, be considered, in theoretical investigations of this sort, in the light of a machine which it has required a certain outlay of labour to construct; the wages which he earns may be looked upon as a fair remuneration for his services, or, if we may so speak, they yield him the common and ordinary rate of profit on his capital, exclusive of a sum to replace its wear and tear, or to supply the place of the old and decayed labourers with new ones. Whether, therefore, a commodity have been produced by the outlay of a capital which it cost a certain quantity of labour to provide, or whether it have been produced by the expenditure of that amount of labour directly upon it, is of no moment. In either case it is the result of the same outlay of labour, or, if it be deemed a better phrase, of capital. There is, in truth, no substantial difference between the manual labour of man and the action of machinery. Men are themselves, in so far as their mere physical powers are concerned, and it is of such only that we are now talking, to be looked upon as capital, or to be considered in the same point of view as the tools or engines with which they perform their tasks; and to say that the exchangeable value of commodities depends on the quantities of capital expended on their production, is not to contradict, but is, in fact, only another way of expressing the identical proposition we have been endeavouring to illustrate.[1]

SECT. V.—*Division of the Produce of Industry, under deduction of Rent, between Capitalists and Workmen.—Definition of Profits.—Mr Ricardo's Theory of Profits; sense in which it is true.—Causes which occasion a Rise or a Fall of Profits.—Influence of the Decreasing Fertility of the Soil and of Taxation on Profits.*

Division of the produce of industry between capitalists and workmen.

Before attempting to investigate the circumstances which determine the rate of profit, it is necessary to be aware of those which determine the proportions in which the whole produce of industry, under deduction of rent, is divided between labourers and capitalists.

This preliminary inquiry may be disposed of in a few words. We have seen, that the whole produce of the land and labour of every civilized society is always divided, in the first instance, into three, and not more than three, portions; the first of which goes to the labourers, the second to the capitalists or proprietors of stock, and the third to the landlords; and we have also seen, that the portion of the produce of industry, or of rent, which belongs to the landlords, as proprietors of the soil, and not as capitalists, is altogether extrinsic to the cost of production; and that the circumstance of the landlords' consenting to give it up, would not occasion any change in the productiveness of industry, or any reduction in the price of raw produce. Supposing, then, that rent is deducted or set aside, it is obvious that all the remaining produce of the land and labour of every country must be primarily divided between the two great classes of labourers and capitalists. And it is further obvious, that were there no taxes in a country, or were the rate of taxation invariable, the proportion of the whole produce of industry, under deduction of rent, falling to the share of the labourers, could not be increased except by an equivalent reduction in the proportion falling to the share of the capitalists, and *vice versa*. Suppose, still better to illustrate this proposition, that the whole produce of industry in Great Britain is represented by the number 1000; suppose farther, that the landlords get 200 of this sum as rent, and that the remaining 800 is divided in equal portions between labourers and capitalists. Under these circumstances, it is quite obvious that nothing could be added to the proportion of the produce, or to the 400, falling to the labourers, except at the expense of the capitalists; nor to the proportion or 400 falling to the latter, except at the expense of the former.

Whether the 800 were increased to 1600, or reduced to 400, so long as those between whom it must be divided receive each a half, their relative condition must continue the same. And hence the propriety of the distinction between proportional and real wages, or wages estimated in parts of the produce raised by the labourer, and those estimated in definite quantities of money or produce. If the productiveness of industry were to diminish, proportional wages might rise, notwithstanding that real wages, or the absolute quan-

---

[1] Sir William Petty stated, so early as 1667, that the value of commodities is always regulated by the quantity of labour required to produce them; there is, however, the same difference between his statements and the analysis and investigations of Mr Ricardo, whom we have principally followed in this section, that there is between the conjectures of Pythagoras respecting the true system of the world and the demonstrations of Newton. But as the statement of Petty is curious, we subjoin it:

"If," says he, "a man can bring to London an ounce of silver out of the earth in Peru in the same time that he can produce a bushel of corn, then one is the natural price of the other; now, if, by reason of new and more easie mines, a man can get two ounces of silver as easily as formerly he did one, then corn will be as cheap at 10s. the bushel, as it was before at 5s. *cæteris paribus.*" (*Treatise of Taxes and Contributions*, ed. 1679, p. 31.)

Division the Pro- uce of In- ustry be- ween Ca- pitalists d Work- men.

tity of the products of industry received by the labourer, might be diminished; and if, on the other hand, the productiveness of industry were to increase, proportional wages might be diminished, while real wages might, at the same time, be increased.

It is plain, therefore, that were taxation unknown or constant, the whole produce of industry, under deduction of rent, would be divided between capitalists and labourers; and that the proportion of that produce falling to either party would vary inversely as the proportion falling to the other—that is, the proportion falling to the capitalists would be increased when that falling to the labourers was diminished, and diminished when it was increased.

efinition profits.

Profits must not, however, be confounded with the produce of industry primarily received by the capitalists. They really consist of the produce, or the value of the produce, remaining to those who employ capital in industrious undertakings, after all their payments to others have been deducted, and after the capital wasted or used in the undertakings has been replaced. If the produce derived from an undertaking, after defraying the necessary outlay, be insufficient to replace the capital expended, a loss will have been incurred; if the capital be merely replaced, and there is no surplus, there will neither be loss nor profit; and the greater the surplus, the greater of course will be the profit. Profits are not measured by the proportion which they bear to the rate of wages, but by the proportion which they bear to the capital by the agency of which they have been produced. Suppose an individual employs a capital equivalent to 1000 quarters of corn in the cultivation of a farm, and that he expends 700 quarters in the payment of wages, and 300 in seed and other outgoings: suppose now that the return to this capital is 1200 quarters. Under these circumstances, the proportion of the produce falling to the labourers as wages, will be to that falling to the capitalists as seven to two; for of the 1200 quarters that fall, in the first instance, to the capitalist, 200 only are profits, 1000 being required to replace the capital he has expended. In this case, therefore, the rate of profit would be said to be twenty per cent., meaning, that the excess of produce belonging to the cultivator, after the capital employed in its production was fully replaced, amounted to twenty per cent. upon that capital.

Ricar- theory profits.

We have been thus particular with respect to the definition of profits, because, from not keeping it sufficiently in view, Mr Ricardo has been led to contend, that the rate of profit depends on the proportion in which the produce of industry, under deduction of rent, is divided between capitalists and labourers; that a rise of profits can never be brought about except by a fall of proportional wages, nor a fall of profits except by a corresponding rise of proportional wages. It is evident, however, that this theory is true only in the event of our attaching a radically different sense to the term profit from what is usually attached to it, and supposing it to mean the real value of the entire portion of the produce of industry falling, in the first instance, to the share of the capitalist, without reference to the proportion which this produce bears to the capital employed in its production. If we understand the terms in this sense, Mr Ricardo's theory will hold universally; and it may be affirmed, that so long as the proportion in which the produce of industry, under deduction of rent, is divided between capitalists and labourers, continues the same, no increase or diminution of the powers of production will occasion any variation in the rate of profit. But if we consider profits in the light in which they are invariably considered in the real business of life—as the produce accruing to the capitalists, after the capital expended by them in payments and outgoings of all sorts is fully replaced—it will immediately be seen, that there are innumerable exceptions to Mr Ricardo's theory.

Profits and Wages.

Profits in agriculture.

It will facilitate the acquisition of clear and precise ideas respecting the circumstances which determine the average rate of profit in different employments, as that term is commonly understood, if we confine our attention, in the first place, to those that determine profits in agriculture,—both because the latter admit of being accurately measured, and because they may be taken as representing profits in other businesses. Agriculture is a branch of industry that must be carried on at all times, and under all circumstances; but it would not be carried on, if it did not, at an average, yield as great a return to the capital vested in it as other businesses; nor would these other businesses be carried on if they yielded a less return than is derived from agriculture. It necessarily follows, therefore, that the returns obtained from agricultural industry, or agricultural profits, may, in ordinary cases, be considered as identical with the returns or profits obtained from other businesses. Whenever, for example, the average return to an outlay of capital or labour worth a hundred quarters of wheat, employed in the cultivation of the soil, amounts to a hundred and ten quarters, we may safely infer that L.100 employed in manufactures is also yielding L.110: for a regard to their own interest will not permit those engaged in such departments to prosecute them for less profit than is obtained in agriculture, and the competition of the agriculturists will not permit them to obtain more.

Circumstances which occasion a rise or fall of profits.

Taking, then, as we are entitled to do, agricultural profits as a standard of all other profits, let us suppose that a landlord employs a capital equal in value to 10,000 quarters, or L.10,000, in the cultivation of an estate; that he expends 5000 quarters, or L.5000, of this capital in seed, in the keeping of horses, and in defraying the wear and tear of implements and machines; and 5000 quarters, or L.5000, in paying the wages of his labourers. Suppose, now, that the return obtained by this landlord is 12,000 quarters, or L.12,000; of which 10,000 quarters, or L.10,000, go to replace his capital, and 1000 quarters, or L.1000, to pay his taxes, leaving 1000 quarters, or L.1000, as profits, being ten per cent. on the capital employed: it is plain from this case (and this case is, in point of principle, the actual case of all cultivators), that the rate of profit may be increased in three, but only in one or other of three, ways, viz. 1, by a fall of wages; 2, a fall of taxes; or, 3, an increased productiveness of industry.

Thus, it is obvious, 1, that if wages were reduced from 5000 to 4000 quarters, profits, supposing other things to be invariable, would be increased from 1000 to 2000 quarters, or from ten to twenty per cent.: if, 2, the burden of taxation were reduced from 1000 to 500 quarters, profits would be increased from 1000 to 1500 quarters, or from ten to fifteen per cent.: and if, 3, owing to the introduction of an improved system of agriculture, the return to a capital of 10,000 quarters were increased from 12,000 to 13,000 quarters, profits, supposing wages still to amount to 5000 and taxes to 1000 quarters, would be increased to 2000 quarters, or to twenty per cent.; and though, in this case, after the productiveness of industry had been increased, wages would form a less proportion of the whole produce of industry than they did previously, it is to be observed, that this diminished proportion is the consequence, and not the cause, of profits having risen; and, therefore, in such cases as this, and they are of very frequent occurrence, it is true to say, that proportional wages fall because profits rise: but the converse of the proposition is not true; for the rise of profits was occasioned by causes that had nothing whatever to do with wages, and which were, in fact, totally independent of them.

It is indeed true, inasmuch as the rise of profits is the result of an increased productiveness of industry, that the real value of the 13,000 quarters will not exceed the real value of the 12,000 previously obtained by the same quantity of labour; but profits, in the sense in which they are practically understood, and as we understand them, do not depend on real values, but on the excess of the commodities produced above the capital expended in their production; and whenever this excess is augmented, without any previous depression in the rate of wages, the rate of profit must evidently be increased by the operation of causes extrinsic to variations in that rate.

Nor is this all. The rate of profit may remain stationary, or rise, though the proportion of the produce of industry falling to the share of the labourer be actually increased. Suppose, to exemplify this, that a landlord employs 1000 quarters of wheat as a capital, 500 of which are expended in seed, keep of horses, &c. and 500 in paying wages; if the produce be 1200 quarters, and the taxes to which he is subjected 100, his profits will amount to 100 quarters, or ten per cent.: suppose now that, owing to the introduction of improved machinery, or improved methods of culture, he only requires to expend 400 quarters in seed, keep of horses, &c. but that wages rise from 500 to 550 quarters, and that the same return is obtained; in this case, supposing taxation to be constant, the profits of the landlord will be increased from ten to fifteen three fourths per cent., though proportional wages have risen from five twelfths to five and a half twelfths of the whole produce.

It may be said, however, that if this increased productiveness were confined to agriculture, and did not extend to most other important businesses, the price of agricultural produce would fall, while that of other produce would remain stationary; and that, in such a case, the profits of agricultural industry, if estimated in money, or in any commodity other than corn, would be diminished in consequence of the rise of wages. This is true; but Mr Ricardo has made no exception, in laying down his theory, in favour of those possible, and indeed frequently occurring cases, when, from any single circumstance, or combination of various circumstances, industry becomes generally more productive, and when, consequently, profits, estimated in money, corn, cloth, or any commodity in extensive demand, would have risen, without their rise having been occasioned by a fall of wages. And it is also true, that an increased productiveness of agricultural industry, whether it have been caused by the introduction of an improved system of agriculture, or by the repeal of restrictions on the importation of corn into a comparatively populous country, most commonly extends itself to other businesses, and has the effect of bringing about a universal rise of profits; for, as raw produce forms the principal part of the labourer's subsistence, and as he obtains a larger quantity in exchange for the same amount of money, after it has fallen in price, his condition is in so far improved; and a stimulus being, in this way, given to population, and the supply of labour increased, wages are reduced, and the rate of profit universally raised.

When industry, instead of becoming more productive, becomes less so, the opposite effects follow. Profits then fall, without any fall having previously taken place in the rate of wages. It is evident, therefore, that the proposition that a rise of profits cannot be brought about otherwise than by a fall of wages, nor a fall of profits otherwise than by a rise of wages, is true only in those cases in which the productiveness of industry and the burden of taxation remain constant. So long as this is the case, or, which is the same thing, so long as the same capital is employed, and the same quantity of produce has to be divided between capitalists and labourers, the share of the one cannot be increased without that of the other being equally diminished; and it is also true, that if profits depended on the proportion in which the produce of industry is divided between capitalists and labourers, they could not be affected by variations in the productiveness, but would be determined wholly by the state of proportional wages. But profits depend, as has been already seen, on the proportion which they bear to the capital by which they are produced, and not on the proportion which they bear to wages. Suppose an individual employs a capital of 1000 quarters, or L.1000, in cultivation; that he lays out half this capital in the payment of wages, and obtains a return of 1200 quarters, or L.1200: in this case, assuming he is not affected by taxation, his profits will amount to 200 quarters, or L.200, being at the rate of twenty per cent., and will be to wages in the proportion of two to five. Suppose, now, that the productiveness of industry is universally doubled, and let it be farther supposed, that the additional 1200 quarters, or L.1200, is divided between the capitalist and his labourers in the former proportion of two to five, or that the capitalist gets 343 quarters, or L.343, of additional profits, and the labourers 857 quarters, or L.857, of additional wages: in this case, both parties will still obtain the same proportions of the produce of industry as before; and if we look only to them, we must say that neither profits nor wages have risen. But when we compare, as is invariably done in estimating profits, the return obtained by the capitalist with the capital he employs, it will be found, notwithstanding the constancy of proportional wages, that the rate of profit has increased from twenty to fifty-four per cent.

Thus, then, it appears, as was previously stated, that profits rise in one or other of the three following ways, viz. 1, from a fall of wages; or, 2, from a fall of taxes directly or indirectly affecting capitalists; or, 3, from an increased productiveness of industry: and they fall, 1, from a rise of wages; or, 2, from an increase of taxes; or, 3, from a diminished productiveness of industry. But they can neither rise nor fall, except from the operation of one or more of the causes now stated.

Influence o
the decreas
ing fertilit
of the soil
on profits.

It is consistent with universal experience, that profits are invariably much higher in colonies, and thinly-peopled countries, than in countries that have been long settled, and where the population is comparatively dense; and that (referring to periods of average duration) their tendency is to fall in the progress of society. This sinking of profits in rich and populous countries has been ascribed by Dr Smith to the competition of capitalists. He supposes that when capital is augmented, its owners endeavour to encroach on each other's employments; and that, in furtherance of their object, they are tempted to offer their goods at a lower price, and to give higher wages to their workmen; which has a twofold influence in reducing profits. This theory was long universally assented to. It has been espoused by MM. Say, Sismondi, and Storch, by the Marquis Garnier, and, with some trifling modifications, by Mr Malthus. But, notwithstanding the deference due to these authorities, it is easy to see that competition can never bring about a general fall of profits. It prevents any one individual, or set of individuals, from monopolizing a particular branch of industry, and reduces the rate of profit in different businesses nearly to the same level; but this is its whole effect. Most certainly it has no tendency to lessen the productiveness of industry, or to raise the average rate of wages or the rate of taxation; and if it do none of these things, it is quite impossible it should lower profits. So long as an individual, employing a capital of 1000 quarters, or L.1000, obtains from it a return of 1200 quarters, or L.1200, of which he has to pay 100 quarters, or L.100, as taxes, so long will his profits continue at ten per cent., whether he have the market to himself, or have 50,000 competitors. It is not competition, but it is the increase of taxation, and the necessity under which a growing society is placed of resorting to soils of less fertility to obtain supplies of food, that are the great causes of that reduction in the rate of profit which usually takes place in advanced periods. When the last lands taken into cultivation are fertile, there is a comparatively large amount of produce to be divided between capitalists and labourers;

and both profits and real wages may, consequently, be high. But with every successive diminution in the fertility of the soils to which recourse is had, the quantities of produce obtained by the same outlays of capital and labour necessarily diminish.[1] And this diminution will obviously operate to reduce the rate of profit—1, by lessening the quantity of produce to be divided between capitalists and labourers; and, 2, by increasing the proportion falling to the share of the latter.

The influence of the decreasing productiveness of the soil, as well on the condition and fortunes of society, as on the rate of profit, is so very powerful, that we shall endeavour to trace and exhibit its operation a little more fully. It has been shown over and over again, that the principle of increase in the human race is so very strong, as not only to keep population steadily up to the means of subsistence, but to give it a tendency to exceed them. It is true, that a peculiar combination of favourable circumstances occasionally causes capital to increase faster than population, and wages are in consequence augmented. But such augmentation is rarely permanent, at least to the whole extent; for the additional stimulus it is almost sure of giving to population seldom fails, by proportioning the supply of labour to the increased demand, to reduce wages to their old level, or to one not much above it. If, therefore, it were possible always to employ additional capital in raising raw produce, in manufacturing that produce when raised, and in conveying the raw and manufactured products from place to place, with an equal return, it is evident, supposing taxation to continue invariable, that, speaking generally, the greatest increase of capital would not occasion any considerable fall in the rate of profit. So long as labour may be obtained at the same rate, and as its productive power is not diminished, so long must the profits of stock continue unaffected. It is evident, then, that the mere increase of capital has, by itself, no lasting influence on wages, and it is obviously the same thing, in so far as the rate of profit is concerned, whether ten or ten thousand millions be employed in the cultivation of the soil, and in the manufactures and commerce of this or any other kingdom, provided the last million so employed be as productive, or yield as large a return, as the first. Now, this is invariably the case with the capital employed in manufactures and commerce. The greatest amount of capital and labour may be employed in fashioning raw produce, and adapting it to our use, and in transporting it from where it is produced to where it is to be consumed, without a diminished return. Whatever quantity of labour may now be required to build a ship or construct a machine, it is abundantly certain that an equal quantity will, at any future period, suffice to build a similar ship, or to construct a similar machine; and although these ships and machines were indefinitely multiplied, the last would be as well adapted to every useful purpose, and as serviceable, as the first. The probability, indeed, or rather the certainty, is, that the last would be much more serviceable than the first. It is not possible to assign limits to the powers and resources of genius, nor consequently to the improvement of machinery, and of the skill and industry of the labourer. Future Watts, Arkwrights, and Wedgwoods, will arise; and the stupendous discoveries of the last and present age will doubtless be equalled, and most probably surpassed, in the ages that are to come. It is therefore clear, that if equal quantities of capital and labour always raised equal quantities of raw produce, the greatest additions that might be made to them would not lessen the capacity of employing them with advantage, or sink the rate of profit. But here, and here only, the bounty of nature is limited, and she deals out her gifts with a frugal and parsimonious hand,

> ———— Pater ipse colendi
> Haud facilem esse viam voluit.

Equal quantities of capital and labour do not always produce equal quantities of raw produce. The soil is of limited extent and limited fertility; and this limitation is the real check—the insuperable obstacle—which prevents the means of subsistence, and consequently the inhabitants, of every country, from increasing in a geometrical proportion, until the space required for carrying on the operations of industry has become deficient.

It is plain that the decreasing productiveness of the soils to which every improving society is obliged to resort, will not, as was previously observed, merely lessen the quantity of produce to be divided between profits and wages, but will also increase the proportion of that produce falling to the share of the labourer. It is quite impossible to go on increasing the cost of raw produce, the principal part of the subsistence of the labourer, by forcing good or taking inferior lands into cultivation, without increasing wages. A rise of wages is seldom indeed exactly coincident with a rise in the price of necessaries, but they can never be very far separated. The price of the necessaries of life is in fact the cost of producing labour. The labourer cannot work, if he be not supplied with the means of subsistence; and though a certain period of varying extent, according to the circumstances of the country at the time, must generally elapse, when necessaries are rising in price, before wages are proportionally augmented, such an augmentation must, in all ordinary cases, be brought about in the end.

It is plain, therefore, inasmuch as there is never any falling off, but a constant increase, in the productiveness of the labour employed in manufacturing and commercial industry, that the subsistence of the labourer could not be increased in price; and, consequently, that it would not be necessary to make any additions to his natural wages, or the wages required to enable him to subsist and continue his race, were it not for the diminished power of agricultural labour, originating in the inevitable necessity under which man is placed, of resorting to inferior soils to obtain larger supplies of raw produce. The decreasing fertility of the soil is, therefore, at bottom, the great and only necessary cause of a fall of profits. The quantity of produce forming the return to capital and labour would never diminish, but for the diminution that uniformly takes place in the productiveness of the soil; nor is there any other physical cause why the proportion of wages to profits should be increased, and the rate of profit diminished, as it uniformly is, in the progress of society.

We have thus endeavoured to exhibit the ultimate influence which the necessity of resorting to poorer lands for supplies of food has on profits and wages. But though this cause of the reduction of profits be "of such magnitude and power as finally to overwhelm every other,"[2] its operations may be, and indeed commonly are, counteracted or facilitated by extrinsic causes. It is obvious, for example, that every discovery or improvement in agriculture, which enables a greater quantity of produce to be obtained for the same expense, has a similar effect on profits, as if the extent of superior soils were increased, and may, for a lengthened period, increase the rate of profit.

Had the inventive genius of man been limited in its powers, and had the various machines and implements used in agriculture, and the skill of the husbandman, speedily attained to their utmost perfection, the rise in the price of raw produce, and the fall of profits consequent to the increase of population, would have been so apparent as to force themselves on the attention of every one. When, in such a state of things, it became necessary to resort to poorer soils to raise an additional quantity of food, a corresponding increase of labour would have been required; for, supposing the perfection of art to be attained, nothing except greater exertion can overcome fresh obstacles. Not only, therefore, would additional labour have been necessary to the production of a greater quantity of food, but it would have been necessary in the precise proportion in which the difficulty of its production was increased; so that, had the arts continued stationary, the price of raw produce would have varied directly with every variation in the qualities of the soils successively brought under tillage.

---

[1] This supposes, of course, either that no improvements are made, or that their influence has been taken into account.

[2] Malthus' Principles of Political Economy, &c. p. 317.

But the circumstances which really regulate the value of raw produce are extremely different. It is true, indeed, that even in those societies that are most rapidly improving, it has, as was previously shown, a constant tendency to rise; for the rise of profits consequent to every invention, by occasioning a greater demand for labour, gives a fresh stimulus to population; and thus, by increasing the demand for food, again inevitably forces the cultivation of poorer soils, and raises prices. But it is evident that improvements render these effects of this great law of nature, from whose all-pervading influence the utmost efforts of human ingenuity cannot enable man to escape, far less palpable and obvious. After inferior soils are cultivated, more labourers are, in most cases, required to raise the same quantities of food; but as the powers of labourers are gradually improved in the progress of society, a much smaller number is required, in proportion to the whole work that is performed, than if no such improvement had taken place. The natural tendency to an increase in the price of raw produce is in this way counteracted. The productive energies of the earth gradually diminish, and we are compelled to resort to less fruitful soils; but the productive energies of the labour employed in their tillage are as constantly augmented by the discoveries and inventions that are always being made. Two directly opposite and continually acting principles are thus set in motion. From the operation of fixed and permanent causes, the increasing sterility of the soil is sure, in the long run, to overmatch the improvements that occur in machinery and agriculture, prices experiencing a corresponding rise, and profits a corresponding fall. Occasionally, however, these improvements more than compensate, during lengthened periods, for the deterioration in the quality of the soils successively cultivated; and a fall of prices and rise of profits take place, until the constant pressure of population has again forced the cultivation of still poorer lands.

In so far as the general principle is concerned, the previous reasoning is applicable alike to the commercial world or to a single nation. It is plain, however, that the fall in the rate of profit, and the consequent check to the progress of society, originating in the necessity of resorting to poorer soils, will be more severely felt in an improving country, which excludes foreign corn from her markets, than in one which maintains an unfettered intercourse with her neighbours. Were a highly manufacturing and commercial country, like England, to deal with all the world on fair and liberal principles, she might avail herself of all those capacities of production which Providence has given to different countries; and besides obtaining supplies of food at the cheapest rate at which they can be raised, the numberless markets to which she could resort would prevent her from feeling any very injurious consequences from the occasional failure of her own harvests, or from deficiencies in one or a few of the sources whence she drew her foreign supplies; so that she would thus go far to secure herself constant plenty, and, what is of hardly less importance, constant steadiness of price. Such a nation would have the foundations of her greatness established on a broad and solid basis; for they would rest, not on the productive powers of her own soil only, but on those of all the countries of the world. And supposing her not to be involved to an unusual degree in war, or subjected to comparatively heavy taxes, her profits would not be reduced, nor would she get clogged in her progress, until the increase of population forced the cultivation of inferior soils in the countries whence she was in the custom of importing corn. And even then she would not be surpassed by her neighbours; her progress being retarded by a cause which equally affects them, her relative power would not be impaired; and should new markets be opened, or new discoveries made, in any quarter of the world, she would reap her full share of the advantage, and be renovated and strengthened for a new career of exertion.

But the case would be very different were foreign raw produce excluded from the markets of a nation like England, which has made an unusual progress in commerce and manufactures, and whose population is therefore comparatively dense. A government which prevents its subjects from exchanging their manufactured goods for the corn of more fertile or less densely-peopled countries, compels them prematurely to resort to poor soils at home; and profits being consequently reduced, the country is made to approach the stationary state at a period when, had the legislature acted on more enlarged principles, she might have been advancing with the same rapidity as before in the career of improvement.

It is needless here to advert to the influence of restrictions on the corn trade in aggravating the evils of scarcity, and occasioning fluctuations of price. Their operation in this respect is too well established to admit of any doubt. But supposing it were otherwise, still it must be obvious, for the reasons stated above, that such restrictions cannot fail to be exceedingly injurious. It may, one should think, be laid down as an axiom, that government should either not interfere at all with industrious undertakings, or interfere only in the view of rendering them more secure or more productive. But to exclude any article, and particularly one so important as corn, when it may be imported cheaper from abroad than it can be raised directly at home, is really to adopt the means most effectual for rendering industry least secure and least productive! It is not merely contradicting the best established principles, but it is employing the power of government to arrest the natural progress of opulence and prosperity, and to accelerate the period of old age, decrepitude, and decay! If we could, by laying out L.1000 on the manufacture of cottons or hardware, produce a quantity of these articles that would exchange for 400 quarters of Polish or American wheat; and if the same sum, when expended in cultivation in this country, would not produce more than 300 quarters; the prevention of importation occasions an obvious sacrifice of 100 quarters out of every 400 consumed in the empire; or, which is the same thing, it occasions an artificial advance of twenty-five per cent. in the price of corn. It is not even true that a system of this sort is, in any respect, advantageous to the landlords or farmers; and to suppose that it can be advantageous to those who are obliged to buy their produce, is too contradictory to merit one moment's attention.

Practically, however, we are not disposed to think that the influence of the existing restrictions on the importation of corn into Great Britain is nearly so injurious as is frequently represented. The fact is, that our average prices have been during the last seven years rapidly approximating to those of the Continent. Owing to the great increase in the imports from Ireland, and still more to the extraordinary improvement made in agriculture since 1825, partly by the greater facilities afforded by steam-navigation for bringing the produce of the more remote districts to market, and partly and principally, perhaps, by the influence of a better system of draining, and of the application of bone-manure, &c., production has latterly shot a-head of population. During the seven years ending with 1837, prices were comparatively low, and were, indeed, taking quality into account, but little, if anything, above their level in the principal markets in the western parts of continental Europe supplied with corn brought from a distance. The pernicious influence of the corn-laws is now principally felt in scarce years, or when the crop is deficient; and as their tendency is to render the country dependent on its own resources, and to hinder corn from being grown abroad for our markets, they must necessarily aggravate, in no common degree, all the mischievous consequences resulting from a bad harvest. Sound policy would, therefore, suggest their repeal, under the conditions, and in the way pointed out, in the article CORN LAWS.

PART IV.

CONSUMPTION OF WEALTH.

Having in the previous sections endeavoured to explain the means by which labour is facilitated, and wealth produced, and to investigate the laws which regulate its distribution among the various classes of society, we come now to the *third* and last division of the science, or to that which treats of the CONSUMPTION of Wealth.

Definition of Consumption.—Consumption the end of Production.—Test of Advantageous and Disadvantageous Consumption.—Error of Dr Smith's Opinions with respect to Unproductive Consumption.—Error of those who contend, that to facilitate Production, it is necessary to encourage Consumption.—Cause of Gluts.—Consumption of Government.—Conclusion.

efinition con- mption.

It was formerly seen, that by production in this science, is not meant the production of matter, that being exclusively the prerogative of Omnipotence, but the giving to matter such a shape as might fit it for ministering to our wants and enjoyments. In like manner, by consumption is not meant the consumption or annihilation of matter, that being as impossible as its creation, but merely *the consumption or annihilation of the qualities which render commodities useful and desirable.* To consume the products of art or industry, is to deprive them of the utility, and consequently of the value, communicated to them by labour. And hence we are not to measure consumption by the magnitude, weight, or number of the products consumed, but exclusively by their value. Large consumption is the destruction of large value, however small the bulk in which it may happen to be compressed.

nsump- n the d of pro- ction.

Consumption, in the sense in which the word is used by political economists, is synonymous with use. We produce commodities only that we may use or consume them. Consumption is the end and object of human industry; production is merely a means to attain that end. All the products of art and industry are destined to be consumed, or made use of; and if the consumption of a commodity fit to be used be deferred, a loss is incurred. Products are intended to satisfy the wants or to add to the enjoyments of their producers; or they are intended to be employed as capital, and made to reproduce a greater value than themselves. In the *first* case, by delaying to use them, we either refuse to satisfy a want, or deny ourselves a gratification;—and in the *second*, by delaying to use them, we allow the instruments of production to lie idle, and lose the profit derivable from their employment.

Test of advantageous consumption.

But though commodities are produced only to be consumed, we must not fall into the error of supposing, that all consumption is equally advantageous to the individual or the society. If an individual employ a set of labourers to build him a house the one summer, and to pull it down the next, their labour, or the capital paid them in exchange for it, and which they consumed during the time they were engaged in this futile employment, is evidently destroyed for ever, and absolutely lost both to their employer and the public; whereas, had he employed them in the raising of corn, or the production of any species of valuable produce, he would have obtained products equal to, or more valuable than, the capital he gave them. The value of the return, or the advantage obtained from the consumption, is, therefore, the true test of advantageous and disadvantageous, or, as it is more commonly termed, of productive and unproductive consumption. Commodities are consumed productively when the advantage or benefit accruing in consequence to their possessors, or when the value of the products obtained in their stead, exceeds their value; and they are consumed unproductively when the value of the advantage or benefit, or that of the new commodities, is less than their value. The prosperity or decay of every nation depends on this balance of consumption and reproduction. If, in given periods, the commodities produced in a country exceed those consumed in it, the means of increasing its capital will be provided, and its population will increase, or the actual numbers will be better accommodated, or both. If the consumption in such periods fully equals the reproduction, no means will be afforded of increasing the stock or capital of the nation, and society will be at a stand. And if the consumption exceed the reproduction, every succeeding period will see the society worse supplied; its prosperity and population will evidently decline, and pauperism will gradually spread itself over the whole country.

It is impossible, however, to fix on any standard by a comparison with which to obtain even a tolerable approximation to the value or advantage of different kinds of consumption. This is a point on which the sentiments of no two individuals ever exactly coincide. The opinions of each will always depend more or less on the situation in which he is placed. The rich man will naturally be inclined to give a greater extension to the limits of advantageous consumption than the man of middling fortune; and the latter than he who is poor. And it is undoubtedly true that a man's expenses should always bear some proportion to his fortune and condition in society; and that what might be proper and advantageous expenditure in one case, might be exceedingly improper and disadvantageous in another. It is, therefore, quite impracticable to frame any system of rules on the subject of expenditure applicable to the case of every individual; and even if it were practicable, there is no ground for thinking that they would be of the smallest utility. The state has no right whatever to control individual expenditure; nor, if it had such a right, could it exercise it without serious injury. The public interest requires that the national capital should, if possible, be constantly kept on the increase; or, which is the same thing, that the consumption of any given period should become the means of reproducing a greater value. But it has been sufficiently proved that this cannot, under any circumstances, be the result of a system of *surveillance* and restriction. Industry and frugality never have been, and never can be, promoted by such means. To render a man industrious, secure him the peaceable enjoyment of the fruits of his industry:—to wean him from extravagance, and make him frugal and parsimonious, allow him to reap all the disadvantage of the one line of conduct, and all the advantage of the other. The poverty and loss of station that inevitably result from improvident and prodigal consumption are a sufficient security against its ever becoming injuriously prevalent. Wherever the public burdens are moderate, property protected, and industry free, the efforts of the great body of the people to rise in the world and improve their condition occasion the continued increase of national wealth. It is idle to expect that all unproductive and unprofitable expenditure should ever be avoided; but the experience of all tolerably well governed states proves, that the wealth productively expended, is always much greater than that expended unproductively.

Luxury not disadvantageous.

It was long a prevalent opinion among moralists, that the labour bestowed on the production of luxuries, and consequently their consumption, was unproductive. But this opinion is now almost universally abandoned. Unless, indeed, all comforts and enjoyments are to be proscribed, it is impossible to say where necessaries end and luxuries begin. But if we are to understand by necessaries such products only as are absolutely required for the support of human life, everything but wild fruits, roots, and water, must be deemed superfluous; and in this view of the matter, the peasantry of Ireland, who live only on potatoes and butter-milk, must be considered as having much more of the character of productive labourers than those of Britain! The mere statement of such a doctrine is sufficient for its refutation. Everything that stimulates exertion is advantageous. The mere necessaries of life may be obtained with comparatively little labour; and those savage and uncivilized hordes, who have no desire to possess its comforts, are proverbially indolent and dissipated. To make men industrious,—to make them shake off that lethargy which is natural to them,—they must be inspired with a taste for the luxuries and enjoyments of civilized life. When this is done, their artificial wants become equally clamorous with those that are strictly necessary, and they increase exactly as the means of gratifying them increase. Wherever a taste for comforts and conveniencies is generally diffused, the wants and desires of man become altogether illimitable. The gratification of one leads directly to the formation of another. In highly civilized societies, new products and new modes of enjoyment are constantly presenting themselves as motives to exertion, and as means of rewarding it. Perseverance is, in consequence, given to all the operations of industry; and idleness, and its attendant train of evils, almost entirely disappear. "What," asks Dr Paley, "can be less necessary, or less connected with the sustentation of human life, than the whole produce of the silk, lace, and plate manufactory? Yet what multitudes labour in the different branches of these arts! What can be imagined more capricious than the fondness for tobacco and snuff? Yet how many various occupations, and how many thousands in each, are set at work in administering to this frivolous gratification!" The stimulus which the desire to possess these articles gives to industry renders their introduction advantageous. The earth is capable of furnishing food adequate for the support of a much greater number of human beings than can be employed in its cultivation. But those who are in possession of the soil will not part with their produce for nothing; or rather, they will not raise at all what they can neither use themselves nor exchange for what they want. As soon, however, as a taste for conveniencies and luxuries is introduced, the occupiers of the ground raise from it the utmost that it can be made to produce, and exchange the surplus for such conveniencies and gratifications as they are desirous of obtaining; and, in consequence, the producers of these articles, though they have neither property in the soil, nor any concern in its cultivation, are regularly and liberally supplied with its produce. In this way, the quantity of necessaries, as well as of useful and agreeable products, is vastly increased by the introduction of a taste for luxuries; and the people are, in consequence, not only better provided for, but their numbers are proportionally and greatly augmented.

It is plain, therefore, that the consumption of luxuries cannot, provided it be confined within proper limits, be justly considered as either disadvantageous or unproductive. If, indeed, a man consume more luxuries than his labour or his fortune enable him to command, his consumption will be disadvantageous. But the same thing will happen if he consume a greater quantity of necessaries than he can afford. The mischief does not consist in the species of articles consumed, but in the excess of their value over the means of purchasing them possessed by the consumers. This, however, is a fault which should always be left to be corrected by the self-interest of those concerned. The poverty and degradation caused by indulging in unproductive consumption is a sufficient guarantee against its ever being carried to an injurious extent. To attempt to lessen unproductive consumption by proscribing luxury, is equivalent to attempting to enrich a country by taking away some of the most powerful motives to production.

Dr Smith's criterion of productive and unproductive consumption.

Dr Smith has given another criterion of productive and unproductive consumption; but his opinions on this point, though exceedingly ingenious, and supported with his usual ability, appear to rest on no solid foundation. He divides society into two great classes. The *first* consists of those who fix, or, as he terms it, "realize their labour in some particular subject, or vendible commodity, which lasts for some time at least after that labour is past;" the *second*, of those whose labour leaves nothing in existence after the moment of exertion, but perishes in the act of performance. The former are said by Smith to be *productive*, the latter *unproductive*, labourers. Not that, in making this distinction, Smith meant to undervalue the services performed by the unproductive class, or to deny that they are often of the highest utility; for he admits that such is frequently the case: but he contends, that these services, however useful, do not augment the wealth of the country; and, consequently, that the commodities consumed by this class are unproductively consumed, and have a tendency to impoverish, not to enrich, society. But, to avoid all chance of misrepresentation, we shall give Dr Smith's opinions in his own words.

"There is one sort of labour," says he, "which adds to the value of the subject upon which it is bestowed; there is another which has no such effect. The former, as it produces a value, may be called productive, the latter unproductive, labour. Thus the labour of a manufacturer adds, generally, to the value of the materials which he works upon, that of his own maintenance, and of his master's profit. The labour of a menial servant, on the contrary, adds to the value of nothing. Though the manufacturer has his wages advanced to him by his master, he, in reality, costs him no expense, the value of those wages being generally restored, together with a profit, in the improved value of the subject upon which his labour is bestowed. But the maintenance of a menial servant never is restored. A man grows rich by employing a multitude of manufacturers; he grows poor by maintaining a multitude of menial servants. The labour of the latter, however, has its value, and deserves its reward, as well as that of the former. But the labour of the manufacturers fixes and realizes itself in some particular subject, or vendible commodity, which lasts for some time at least after that labour is past. It is, as it were, a certain quantity of labour stocked and stored up, to be employed, if necessary, upon some other occasion. That subject, or, what is the same thing, the price of that subject, can afterwards, if necessary, put into motion a quantity of labour equal to that which had originally produced it. The labour of the menial servant, on the contrary, does not fix or realize itself in any particular subject or vendible commodity. His services generally perish in the very instant of their performance, and seldom leave any trace or value behind them for which an equal quantity of service could afterwards be procured.

"The labour of some of the most respectable orders in the society is, like that of menial servants, unproductive of any value, and does not fix or realize itself in any permanent subject or vendible commodity, which endures after that labour is past, and for which an equal quantity of labour could afterwards be procured. The sovereign, for example, with all the officers both of justice and war who serve under him, the whole army and navy, are unproductive labourers. They are the servants of the public, and are maintained by a part of the annual produce of the industry of other people. Their service, how honourable, how necessary, or how useful soever, produces nothing for which an equal quantity of service can afterwards be procured. The protection, security, and defence of the commonwealth, the effect of their labour this year, will not purchase its protection, security, and defence for the year to come. In the same class must be ranked some both of the gravest and most important, and some of the most frivolous professions: churchmen, lawyers, physicians, men of letters of all kinds; players, buffoons, musicians, opera-singers, opera-dancers, &c. The labour of the meanest of these has a certain value, regulated by the very same principles which regulate that of every other sort of labour; and that of the noblest and most useful produces nothing which could afterwards purchase or procure an equal quantity of labour. Like the declamation of the actor, the harangue of the orator, or the tune of the musician, the work of all of them perishes in the very instant of its production." (*Wealth of Nations*, p. 146.)

r Smith's istinction etween e different classes f society own to e ill unded.

It will not, we think, be very difficult to show the fallacy of the distinction Dr Smith has here endeavoured to establish between the labour, and consequently also the consumption, of the different classes of society. To begin with the case of the menial servant:—Smith says that his labour is unproductive, because it is not realized in a vendible commodity, while the labour of the manufacturer is productive, because it is so realized. But of what, may we ask, is the labour of the manufacturer really productive? Does it not consist exclusively of comforts and conveniencies required for the use and accommodation of society? The manufacturer is not a producer of matter, but of *utility* only. And is it not obvious that the menial servant is also a producer of utility? If, for example, the labour expended in converting the wool when in the fleece into a coat be, as it unquestionably is, productive, then surely the labour expended in cleaning and brushing the coat, and rendering it fit to be worn, must be so too. It is universally allowed, that the labour of the husbandman in raising corn, beef, and other articles of provision, is productive; but if so, why is the labour of the menial servant who performs the indispensable task of preparing and dressing these articles, and fitting them to be used, to be stigmatized as unproductive? It is clear there is no difference whatever between the two species of labour—that they are either both productive, or both unproductive. To produce a fire, is it not quite as necessary that coals should be carried from the cellar to the grate, as that they should be carried from the bottom of the mine to the surface of the earth? And if it be said that the miner is a productive labourer, must we not say as much of the servant employed to make and mend the fire? The whole of Dr Smith's reasoning proceeds on a false hypothesis. He has made a distinction where there is none, and can be none. The end of all human exertion is the same—that is, to increase the sum of necessaries, comforts, and enjoyments; and it must be left to the judgment of every man to determine what portion of these he will have in the shape of menial services, and what in the shape of material products. It is an error to suppose that a man is impoverished by maintaining menial servants, any more than by indulging in any other species of expense. It is true, he will be ruined if he keep more servants than he has occasion for, or can afford to pay; but his ruin would be equally certain were he to purchase an excess of food or clothes, or to employ more workmen in any branch of manufacture than are required to carry it on, or than his capital could employ. The keeping of two ploughmen when one only might suffice, is as improvident and wasteful as the keeping of two footmen to do the business of one. It is in the extravagant quantity of the commodities we consume, or of the labour we employ, and not in the particular species of commodities or labour, that we must seek for the causes of impoverishment.

Case of the physician.

The same reasoning applies to all the other cases mentioned by Smith. Take, for example, the case of the physician. He tells us that he is an unproductive labourer, because he does not directly produce something that has exchangeable value. But if he do the same thing indirectly, what is the difference? If the exertions of the physician be conducive to health, and if, as is undoubtedly the case, he enable others to produce more than they could do without his assistance, he is indirectly, at least, if not directly, a productive labourer. Dr Smith makes no scruple about admitting the title of the workman employed to repair a steam-engine to be enrolled in the productive class; and yet he would place a physician, who had been instrumental in saving the life of an Arkwright or a Watt, among those that are unproductive! It is impossible that these inconsitsencies and contradictions should have occurred to Smith; and the errors into which he has fallen in treating this important branch of the science, show in the strongest manner the necessity of advancing with extreme caution, and of subjecting every theory, how ingenious soever it may appear when first stated, to a severe and patient examination.

The amusements furnished by players, singers, and so forth, come under the description of luxuries, and have the same effect on the public wealth as the introduction of a taste for tobacco, tea, or other superfluities. They create new wants, and, by so doing, stimulate industry to procure the means of gratifying them. They are really, therefore, a means of production; and while they furnish elegant and amusing recreation, they add to the mass of useful material products.

Public functionaries productive labourers.

The productiveness of the higher class of functionaries is still more obvious. Far, indeed, from being unproductive, they are, when they discharge properly the duties of their high station, the most productive labourers in a state. Smith says, that the results of their service, that is, to use his own words, "the protection, security, and defence of the commonwealth any one year, will not purchase its protection, security, and defence for the year to come." But this is plainly an error. We do not say that the protection and security afforded by good government is directly a cause of wealth; but it is plain that, without it, the productive powers of industry could not be brought into efficient action. Smith allows that the material products produced by the society one year, form the means of producing its supplies of necessaries, conveniencies, and enjoyments during the following year. But without the security and protection afforded by government, these products would either not exist at all, or their quantity would be very greatly diminished. How, then, is it possible to deny that those whose labour is necessary to afford this security are productively employed? Take the case of the labourers employed to construct fences; no one ever presumed to doubt that their labour is productive; and yet they do not contribute directly to the production of corn or any other valuable product. The object of their industry is to give protection and security; to guard the fields that have been fertilized and planted by the husbandman from depredation; and to enable him to prosecute his employments without having his attention distracted by the care of watching. But if the security and protection afforded by hedgers and ditchers justly entitle them to be classed among those who contribute to enrich their country, on what principle can the labours of those public servants who protect property in the mass, and render every portion of it secure against hostile aggression, and the attacks of thieves and plunderers, be said to be unproductive? If the labourers who protect a single corn-field from the neighbouring crows and cattle be productive, then surely the judges and magistrates, the soldiers and sailors, who protect every field in the empire, and to whom it is owing that every class of inhabitants feel secure in the enjoyment of their property, rights, and privileges, have a right to be classed among those whose services are supereminently productive.

That much wealth has been unproductively consumed by the servants of the public, both in this and other countries, it is impossible to doubt. But we are not to argue, from abuses extrinsic to a beneficial institution, against the institution itself. If the public pay their servants excessive salaries, or employ more than are required for the purposes of good government and security, it is their own fault. Their conduct is similar to that of a manufacturer who should pay his labourers comparatively high wages, and employ more of them than he has occasion for. But though a state or an individual may act in this foolish and extravagant manner, it would be not a little rash thence to conclude that all public servants and all manufacturing labourers are unproductive! If the establishments which provide security and protection be formed on an extravagant scale, if we have more judges or magistrates, more soldiers or sailors, than are necessary, or if we pay them larger salaries than would suffice to procure the services of others quite as competent to discharge their duties, let their numbers and their salaries be reduced. The excess, if there be any, is not a fault inherent in the nature of such establishments, but results entirely from the extravagant scale on which they have been arranged.

Consumption ought not to be encouraged for the sake of stimulating production.

But, in showing that Dr Smith was mistaken in considering the consumption of menial servants, and of lawyers, physicians, and public functionaries, unproductive, we must beware of falling into the opposite extreme, and of countenancing the erroneous and infinitely more dangerous doctrine of those who contend that consumption, even when most unproductive, should be encouraged as a means of stimulating production, and of increasing the demand for labour! The consumption of the classes mentioned by Smith is advantageous, because they render services in return, which those who employ them, and who are the only proper judges in such a case, consider of greater value than the wages they pay them. But the case would be totally different were government, and those who employ labourers, to do so, not in order to profit by their services, but to stimulate production by their consumption. It is a fallacy and an absurdity to suppose that production is ever encouraged by a wasteful consumption of the products of industry. A man is stimulated to produce when he finds a ready market for the produce of his labour, that is, when he can readily exchange them for other products. And hence the true and only encouragement of industry consists, not in the increase of wasteful and improvident consumption, but in the increase of production. Every new product necessarily forms a new equivalent for, or a new means of, purchasing some other product. It must always be remembered, that the mere existence of a demand, how intense soever it may be, cannot of itself be a means of encouraging production. To become a real demander, a man must not only have the will, but also the power, to purchase the commodity he wishes to possess; or, in other words, he must be able to offer an equivalent for it. It is not in the nature of things that there can be any limits to our wish to possess the products of art and industry. The power to give effect to our wishes, or to furnish equivalents for the things we are desirous to obtain, is the only desideratum. The more, therefore, that this power is increased, that is, the more industrious individuals become, their means of buying the products of others will be proportionally increased, and the market rendered so much the more extensive.

Unproductive consumption not necessary to prevent gluts.

M. Sismondi and Mr Malthus have indeed contended, in opposition to this doctrine, that the productiveness of industry may be carried to excess, and that where there are great facilities of production, a large unproductive consumption is necessary to stimulate industry, and prevent the overloading of the market. But if we attend to the motives which make men engage in any branch of industry, we shall be satisfied that the apprehensions of these writers are unfounded, and that the utmost facility of production can never be productive of a permanent glut of the market, or require to be counteracted by means of unproductive expenditure. In exerting his productive powers, every man's object is either directly to consume the produce of his labour himself, or to exchange it for such commodities as he may wish to get from others. If he do the first,—if he directly consume the produce of his industry, there is an end of the matter, and it is evident that no conceivable increase of such produce could occasion a glut: If he do the second,—if he bring the produce of his industry to market, and offer it in exchange for other things, then, and then only, there may be glut; but why? Not because there has been an excess of production, but because the producers have not properly adapted their means to their ends. They wanted, for example, to obtain silks, and they offered cottons in exchange for them; the holders of silks being, however, already sufficiently supplied with cottons, wanted broad cloths. The cause of the glut is therefore obvious. It consists not in over-production, but in the production of cottons, which were not wanted, instead of broad cloths, which were. Let this error be rectified, and the glut will disappear. Even supposing the proprietors of silks to be not only supplied with cottons, but with cloth and every other commodity that the demanders could produce, it would not invalidate the principle for which we are contending. If those who want silks cannot get them from the holder by means of an exchange, they have an obvious resource at hand,—let them cease to produce the things which they do not want, and directly produce the silks which they do want, or substitutes for them. It is plain, therefore, that the utmost facility of production can never be a means of overloading the market. Too much of one thing may occasionally be produced; but it is quite impossible that there should be too great a supply of everything. For every excess on the one hand there is a corresponding deficiency on the other. The fault is not in producing too much, but in producing commodities which do not suit the tastes of those with whom we wish to exchange them, or which we cannot ourselves consume. If we attend to these two grand requisites, we may increase the power of production a ten or a twenty times, and we shall be as free of all excess as if we diminished it in the same proportion. Unproductive consumption is not therefore required to prevent the overloading of the market; and though it were, no government would be justified in carrying it on for such a purpose.[1]

---

[1] M. Say was the first who showed, in a satisfactory manner, that effective demand depends upon production. (See his chapter *De Debouchés*.) But the principles from which his conclusions are drawn had been stated so early as 1752, in a tract of Dean Tucker, entitled Queries on the late Naturalization Bill. As this tract is now become of rare occurrence, we subjoin the queries referred to.

Consumption of Wealth.

It must, however, be remembered, consistently with what has been previously advanced, that in deciding as to the character of the consumption or expenditure of any quantity of wealth, we must look at its indirect and ultimate, as well as its direct and immediate, effects. An outlay of capital or labour which, if we take its immediate results only into account, we should pronounce improvident and unproductive, may yet be discovered, by looking at it in its different bearings, and in its remote influences, to be distinctly the reverse; and it is also true, that cases frequently occur in which that expenditure which is ruinous to the individual may not be injurious, but beneficial, to the state.

Montesquieu has said, "*Si les riches ne dépensent pas beaucoup, les pauvres mourront de faim.*"[1] The truth of this proposition has, however, been disputed; nor is this to be wondered at, as it may be either true or false according to the sense in which it is understood. If it be construed to mean that a rich man will be able directly to employ a greater number of servants or labourers if he spend his revenue in luxurious accommodations than if he lay out a part of it on the improvement of his estate, or accumulate it as a provision for his younger children, it is plainly erroneous. The demand for labour cannot be sensibly increased without an increase of capital; and it is quite impossible for those who spend their whole revenue on immediate gratifications to amass any capital, or consequently to employ an additional individual. But the proposition advanced by Montesquieu should not be interpreted in this confined sense, or as referring only to the influence of the expenditure of wealthy individuals on their own demand for labour, but as referring to its influence on that of the society; and if we so interpret it, and suppose it to mean that the lavish expenditure and luxury of the great and the affluent becomes a means of materially benefiting the poor, by exciting the emulation of others, who cannot expect, except through an increase of industry and economy, to be able to indulge in a similar scale of expense, it will, we apprehend, be found to be perfectly correct. To suppose, indeed, that the passion for luxurious gratifications should decline amongst the rich, and that men should notwithstanding continue equally industrious, is a contradiction. Riches are desirable only because they afford the means of obtaining these gratifications; and so powerful is the influence of a taste for them, that it may be doubted whether the extravagance which has ruined so many individuals, has not been, by giving birth to new arts and new efforts of emulation and ingenuity, of material advantage to the public.

These remarks are not made in the view of countenancing extravagant expenditure, but merely to show that those who attempt to decide as to the influence, in a public point of view, of any outlay of wealth, without endeavouring to appreciate and weigh its remote as well as its immediate effects, must, when they are right in their conclusions, be so only through accident. But without insisting farther on this point, it is abundantly certain that there is nothing to fear from the improvidence of individuals. There is not, as has been already observed, an instance of any people having ever missed an opportunity to save and amass; and in all tolerably well governed countries the principle of accumulation has always had a marked ascendency over the principle of expense.

Individuals are fully sensible of the value of the articles they expend; for in the vast majority of instances they are the produce of their own industry and frugality; and they rarely consume them unless in order to subsist, or to obtain some equivalent advantage. Such, however, it must be allowed, is not often the case with the consumption of governments and their servants. They do not consume their own wealth, but that of others; and this circumstance prevents them from being so much interested in its profitable outlay, or so much alive to the injurious consequences of wasteful expenditure, as their subjects. But economy on the part of governments, though more difficult to practise, is of infinitely greater importance than economy on the part of individuals. A private gentleman may, inasmuch as he is master of his own fortune, dispose of it as he pleases. He may act on the erroneous principle of profusion being a virtue, or he may attempt to excite the emulation and industry of his fellow-citizens by the splendour of his equipages and the magnificence of his mode of living. But government can with propriety do none of these things. It is merely a trustee for the affairs of others; and it is consequently bound to administer them as economically as possible. Were the principle admitted that government might raise money, not for the protection and good government of the state, but in order to excite industry and ingenuity by the pressure of taxation, or the luxury of public functionaries, an avenue would be opened to every species of malversation. It is indeed pretty certain that no people would submit to be taxed for such purposes; but if they did, the flagrant abuses to which it would inevitably lead could scarcely fail of ending either in revolution or in national poverty and degradation. Economy in expenditure is, upon all occasions, the first virtue of a government, and the most pressing of its duties.

Conclusion.

We have now seen how labour may be rendered most productive of wealth—how that wealth is distributed among the various classes of society—and how it may be most advantageously consumed. We have seen the indissoluble connection between private and public opulence; that whatever has any tendency to increase the former, must, to the same extent, increase the latter; and that SECURITY OF PROPERTY, FREEDOM OF INDUSTRY, AND MODERATION IN THE PUBLIC EXPENDITURE, are the only, as they are the certain, means by which the various powers and resources of human talent and ingenuity may be called into action, and society made continually to advance in the career of wealth and civilization. Every increase of security or of freedom is a benefit, as every diminution, whether of the one or the other, is an evil. It is by the spontaneous and unconstrained efforts of individuals to improve their condition and rise in the world, that nations become rich and powerful. The labour and the savings of individuals are at once the source and the measure of national opulence and public prosperity. They may be compared to the drops of dew, which invigorate and mature all vegetable nature. None of them has singly any perceptible influence; but we owe the foliage of summer and the fruits of autumn to their combined action. (C. C.)

"Whether it is possible, in the nature of things, for all trades and professions to be overstocked? And whether, if you were to remove any proportional number from each calling, the remainder would not have the same grounds of complaint they had before?

"Whether, in fact, any tradesman thinks there are too many of other occupations to become his customers; though narrow selfish views lead him to wish there were fewer of his own trade?

"If a particular trade be at any time overstocked, will not the disease cure itself? That is, will not some persons take to other trades, and fewer young people be bred up to that which is least profitable? And whether any other remedy but this is not, in fact, curing one transient disorder by bringing on many which are dangerous, and will grow inveterate?

"Whether it is not an infallible maxim, that one man's labour creates employment for another?" (P. 13.)

For a farther demonstration of the same principle, see Mill's Commerce Defended, p. 80.

[1] *Esprit de Loix*, liv. vii. cap. 4.

POLL, a word used in ancient writings for the head. Hence to poll is either to vote, or to enter down the names of those persons who give their votes at an election.

Poll-*Money*, or *Capitation*, a tax imposed by authority of parliament on the person or head, either on all indifferently, or according to some known mark or distinction. Thus by the statute 18 Car. II. every subject in the kingdom was assessed by the head, or poll, according to his degree; a duke L.100, a marquis L.80, a baronet L.30, a knight L.20, an esquire L.10, and every single private person 12d. This was no new tax, as appears by former acts of parliament.

POLLARD, or Crocard, the name given to a sort of base money current in Ireland in the time of Edward I. (See Simon's *History of Irish Coins*, p. 15.)

POLLEN, the fecundating or fertilizing dust contained within the antheræ or tops of the stamina, and dispersed upon the female organ when ripe, for the purposes of impregnation. (See Botany.)

POLLICIS Pressio, and Pollicis Versio, were used at the combats of gladiators as signals of life or death to the vanquished combatant; in other words, to the victor to spare or take the life of his antagonist. The *pollicis pressio*, by which the people granted life to the prostrate gladiator, was no more than a clenching of the fingers of both hands together, and so holding upright the two thumbs close together. The *pollicis versio*, which authorized the victor to kill the vanquished as a coward, was the bending back of the thumbs. Such is the opinion of Dacier; but others say that the *pollicis pressio* was when the people held up one hand with the thumb bent, and the *pollicis versio* when they showed the hand with the thumb raised. Authors, however, are not perfectly agreed on this matter; though the phrases *pollicem premere* and *pollicem vertere* frequently occur in the Latin classics as indications of the people's will that a gladiator should live or die.

POLLIO, Caius Asinius, a celebrated Latin poet and orator, was of consular dignity, and composed some tragedies which were much esteemed, but are now unfortunately lost. He was the first who opened at Rome a library for the use of the public. Being the friend of Mark Antony, he was prevented from complying with the solicitations of Augustus, who pressed him to embrace his party. At length Augustus having written some verses against Pollio, he was urged to answer them; upon which he observed, "I shall take care of writing against a man who has the power of proscribing us." He is praised by Virgil and Horace, both of whom he patronized.

There was another *Pollio*, a friend of Augustus, who used to feed his fishes with human flesh. This cruelty was discovered when one of his servants broke a glass in the presence of Augustus, who had been invited to a feast. The master ordered the servant to be seized, but he threw himself at the feet of the emperor, and begged him to interfere, and not suffer him to be devoured by fishes. Upon this the grounds of his apprehension were examined; and Augustus, astonished at the barbarity of his favourite, caused the servant to be dismissed, all the fish-ponds to be filled up, and the crystal glasses of Pollio to be broken in pieces.

POLLOOR, a town of Hindustan, in the Carnatic, seventy-seven miles south-west from Madras. Long. 79. 15. E. Lat. 12. 30. N.

POLLUX, the son of Tyndareus king of Amyclæ, and of Leda, according to the tradition followed by Homer, was by late writers, along with his sister Helen, made the child of Jupiter, who gained the affections of Lydia in the form of a swan. He was the brother of Castor and Clytemnestra, and was born in the island Pephnos, on the coast of Laconia. Pollux was distinguished for his skill in boxing and wrestling, whilst Castor was famed for his horsemanship. They both took an active part in the hunt of the Calydonian boar, and joined Jason in his search for the golden fleece. On their return they were invited by their cousins Lynceus and Idas, the sons of Aphareus, to attend their marriage with Phœbe and Hilæira, daughters of Leucippus, prince of Messene. They, however, became so enamoured of the two brides, that they forcibly attempted to carry them off, when Castor was killed by Idas. Jupiter, enraged at this proceeding, struck Idas with a thunderbolt; and, to comfort Pollux, offered him his choice of immortality, or, if he preferred it, to live and die alternately with his brother. He chose the latter. Another tradition makes Pollux show his fraternal love by dividing his immortality in such a way that Castor lived one day and Pollux the next; but Homer does not allude to this. Pollux was said to have married Phœbe, daughter of Leucippus, and to have had by her Mnesileus. Having had a dispute with his cousin Idas respecting the division of some spoil they had driven from Messenia, he is represented by one tradition as having perished by the hands of Idas.

Pollux, *Julius*, a Greek writer of antiquity, was born at Naucrates, a town in Egypt, and flourished in the reign of the Emperor Commodus. He was educated under the Sophists, and made great progress in grammatical and critical learning. Having taught rhetoric at Athens, he became so famous that he was made preceptor of the Emperor Commodus. He drew up for the use of the latter, and inscribed to him, whilst his father Marcus Antoninus was living, an *Onomasticon*, or Greek vocabulary, which he divided into ten books. It is extant, and contains a vast variety of synonymous words and phrases, ranged under the general classes of things. It was intended to facilitate the knowledge of the Greek language to the young prince; and it is still very useful to all who have a mind to be perfect in that tongue. The first edition of the *Onomasticon* was printed at Venice by Aldus in 1502, and a Latin version was afterwards published along with it; but there was no correct and handsome edition of this work till that of Amsterdam, 1706, in folio, by Lederlinus and Hemsterhusius. Lederlinus went through the first seven books, and corrected the text and the version, subjoining his own along with the notes of Salmasius, Vossius, Valesius, and Kuhnius. Pollux wrote many other things, none of which remains. He lived to the age of fifty-eight. Philostratus and Lucian have both treated him with much contempt and ridicule. (Philostrat. *de Vit. Sophist.* lib. ii.; and Lucian *in Rhetorum Præceptore*.)

POLO, a small island, one of the Philippines, off the western coast of Luzon, about the fifteenth degree of north latitude. It is twenty-five miles in length by three in average breadth.

POLOONSHAH, a small town and district of Hindustan, in the province of Hyderabad, tributary to the nizam. It is situated in a rich and luxuriant valley, and has a fort 300 yards square, with a large round tower at each angle. It is seventy miles north-west from Rajahmundry. Long. 81. 10. E. Lat. 17. 35. N.

POLTROON, or Poltron, a coward or dastard, wanting the courage requisite to perform anything great or noble. The word is borrowed from the French, who, according to Salmasius, derived it *a pollice truncato;* because anciently those who wished to avoid going to the wars cut off their thumb. But Ménage, with more probability, derives it from the Italian *poltrone*, and that from *poltro*, a bed; because timorous and pusillanimous people take pleasure in lying a-bed. Others, again, derive the word from the Italian *poltro*, a colt, because of that creature's readiness to run away.

POLYÆNUS, the name of many famous men recorded by the ancient writers. Amongst them was Julius Polyænus, of whom we have some Greek epigrams extant in the first book of the *Anthologia*. The Polyænus whom it most concerns us to know about, is the author of the eight books of the Stratagems of Illustrious Commanders in War. He was probably a Macedonian, and perhaps a soldier in the early part of his life; but of this there is no certainty. He was undoubtedly a rhetorician and a pleader of causes; and, from the dedication of his work to the Emperors Antoninus and Verus, he appears to have lived towards the latter part of the second century. The *Stratagemata* were published in Greek by Isaac Casaubon, with notes, 1589, in 12mo; but no good edition of them appeared till that of Leyden, published in 1690, in 8vo.

We have in this work the various stratagems employed by above three hundred captains and generals of armies, chiefly Greeks and barbarians, for the Romans seldom resorted to such arts; and, besides, Polyænus has shown that he was little acquainted with Roman affairs. A great number of these stratagems appear to us to be ridiculous or impracticable; and neither the generals, nor even common soldiers, of our days, would be found simple enough to be caught by them. Few of the latter order indeed are capable of reading Polyænus's Stratagems; and if they were, they would reap but little benefit from the book. It is useful, however, to such as study the Greek language and antiquity; for many things will be found in it illustrative of the customs and opinions of ancient times. The sixth and seventh books are both imperfect.

Polyænus composed several other works besides the *Stratagemata*. Stobœus has produced some passages out of a book *De Republica Macedonum;* and Suidas mentions a piece concerning the Thebans. If death had not prevented him, he would have written Memorabilia of the Emperors Antoninus and Verus, which he promised to undertake in the preface to his sixth book of Stratagems. Casaubon, in the dedication of Polyænus to Mornæus, calls him an elegant, acute, and learned writer.

POLYANTHEA, a collection of common-places arranged in alphabetical order, for the use of orators, preachers, and others. The word is formed from the Greek ϖολυς, *much*, and ἀνθος, *flower*, and has much the same meaning with anthology or florilege. The first author of the Polyanthea was Dominic Nanni di Mirabellio, whose labour has been improved on by Amantius and Torsius; and since their time by Langius, under the title of *Polyanthea Nova*, 1613.

POLYBIUS, a celebrated Greek historian, was the son of Lycortas, a native of Megalopolis, in Arcadia, who succeeded Philopœmen in the chief direction of the Achæan league. His father, therefore, must have been one of the most distinguished men of his time; and we find him accordingly taking part in the principal transactions of his country. The exact date of his birth is unknown, but it is generally believed that it took place between B. C. 210–200; and his death was, therefore, not earlier than B. C. 129, as he lived to the advanced age of eighty-two. Plutarch tells us that the character of Polybius was formed under the eye of Philopœmen; and that at the funeral of that general he carried the urn which contained his ashes, B. C. 182. The following year he was, along with his father and the son of the celebrated Aratus, appointed as ambassador, to return thanks to Ptolemy Epiphanes for the assistance which he had offered to the Achæans; but the death of that prince took place before the ambassadors left the Peloponnesus. In the war which arose between the Romans and Perseus king of Macedonia, the opinion of Polybius and his father Lycortas was, that the Achæans should observe a strict neutrality; but they were overruled, and the Achæans were implicated in the ruin of Perseus. To break the spirit of the Achæans, and to prevent any further attempts at insurrection, more than a thousand of the principal citizens were sent to Rome, and afterwards dispersed throughout the different cities of Italy. Polybius was one of these exiles; but he was so far favoured that he was allowed to remain in Rome, where he resided for sixteen years, from B. C. 167 to 151. He became the intimate friend and instructor of Scipio the younger, at that time only eighteen years old, and who afterwards showed how much benefit he had derived from the care Polybius bestowed on his education. At last, through the influence of Scipio and Cato, the senate was prevailed on to allow the Achæan exiles to return to their country; but of the original thousand only three hundred survived to enjoy the permission thus granted to them. Polybius seems now to have employed his time chiefly in travelling, with the view of acquiring more accurate notions of geography. He examined with great care and minuteness the passes of the Alps, that he might be enabled to give a correct account of the passage of Hannibal. He afterwards visited Gaul, Spain, and Africa, to which latter country he accompanied, Scipio, B. C. 146, when that general took and destroyed Carthage. But the calamities of his own unhappy country called him away, and he hurried to the Peloponnesus, where his presence, however, was unable to save Corinth from the fate which had overtaken Carthage. He did all in his power to prevail on his countrymen to submit to a fate which they only made worse by resistance; and the Roman deputies felt such reliance on his good intentions, that they appointed him to the office of judge in all disputes that might arise in any part of the Peloponnesus. He gradually acquired the esteem of his countrymen, and many of the cities of Greece erected statues to his honour. He subsequently extended his travels into Egypt, which he visited in the reign of Ptolemy Physcon. Whether he was present with Scipio at the siege of Numantia, B. C. 134, we are nowhere told; but he left behind him a work on the subject. He also wrote a biographical sketch of Philopœmen, a work on Military Tactics, and another on the Equatorial Regions.

His principal work, however, was entitled General History, though it referred more particularly to a space of fifty-three years (from 220 to 168 B. C.), from the commencement of the second Punic war, where the historian Timæus, and Aratus of Sicyon, had stopped, to the defeat of Perseus, king of Macedonia, by the Romans. It was divided into forty books, of which we now only possess the first five entire, and rather long fragments of most of the others. The first two books are occupied with introductory matter, giving a sketch of the events that happened anterior to the second Punic war. He explains the causes which gave rise to the first Punic war, and then relates the various events which took place during the twenty-four years it lasted. He gives also some account of the contest which arose between the Carthaginians and their stipendiaries. The second book contains the wars of the Æolians, Illyrians, Achæans, the expeditions of the Romans against the Illyrians and Gauls, and the transactions of Antigonus king of Macedonia, and Cleomenes king of Sparta, occupying a period of seventeen years, from B. C. 237 to 220. The third book enters into what is more properly the subject of his history, and, after explaining what he considers to be the true causes of the second Punic war, follows the path of Hannibal's victories as far as the battle of Cannæ, B. C. 216. Yet it would appear that he was defective in method, as the fourth book carries us back to anterior events, which had happened in 220, 219, 218, B. C. After a sketch of the people of the East during the reign of Philip, son of Demetrius king of Macedonia, of Ariarathes king of Cappadocia, of Antiochus king of Syria, and Ptolemy Philopator king of Egypt, this book traces the history of wars and seditions in Greece. In the fifth book we have the victories of Philip, the wars in Syria between Antiochus and Ptolemy, and the confederated arms of Greece turned against Rome. It would be useless to give any detailed account of the fragments of the thirty-five books that have been preserved; but we know that the thirty-ninth book ended with the destruction of Corinth, B. C. 146.

There have been many editions of this work, but the most critical is that of J. Schweighäuser, eight vols. 8vo, Leipzig. 1789–1795. It has been translated into English by Hampton; into French by Folard, six vols. Par. 1727, with numerous plates and critical annotations; into German by Chr. Seybold, Lemgo; 1779–1783, and by L. Storch, Prenzl. 1828. See *Polybii et Appiani Historiarum Excerpta Vaticana recognita a J. F. Lucht*, Altona, 1830.

POLYCARP, one of the most ancient Fathers of the Christian church, was born towards the end of the reign of Nero, probably at Smyrna, where he was educated at the expense of Calista, a noble matron distinguished alike by her piety and charity. He was unquestionably a disciple of St John the Evangelist, and he conversed familiarly with others of the apostles. When of a proper age, Bucolus ordained him a deacon and a catechist of his church; and upon his death he succeeded Bucolus in the bishopric, to which he is said to have been consecrated by St John, who also directed his Apocalypse, amongst others, to him, under the title of "the angel of the church of Smyrna." When the controversy about the observation of Easter began to run high between the eastern and western churches, he went to Rome to discourse with those who were of the opposite party. The Roman see was then occupied by Anicetus, with whom he had many conferences, which were carried on in the most amicable manner; and though neither of them could bring the other to embrace his opinion, they both retained their own sentiments without violating that charity which is the great law of religion.

Whilst at Rome he particularly opposed the heresies of Marcian and Valentinus. His conduct on this occasion is related by Irenæus, who informs us, that when Polycarp passed Marcian in the street without speaking, Marcian said, "Polycarp, own us;" to which he replied with indignation, "I own thee to be the first-born of Satan." Irenæus adds, that when any heretical doctrines were spoken in his presence, he would stop his ears and say, "Good God, to what times hast thou reserved me, that I should hear such things," and immediately left the place. He was accustomed to mention, that St John, going into a bath at Ephesus, and finding in it Cerinthus the heretic, immediately started back without bathing, crying out, "Let us run away, lest the bath should fall upon us whilst Cerinthus, the enemy of truth, is in it." Polycarp governed the church of Smyrna with apostolic purity, till he suffered martyrdom in the seventh year of Marcus Aurelius. The manner of his death is thus related. The persecution waxing hot at Smyrna, and many having sealed their faith with their blood, the general cry was, "Away with the impious; let Polycarp be sought for." Upon this he privately withdrew into a neighbouring village, where he continued for some time praying day and night for the peace of the church. He was thus employed, when one night he fell into a trance and dreamed that his pillow took fire, and was burned to ashes. When he awoke, he told his friends the circumstance, and pronounced it a presage that he should be burned alive for the cause of Christ. Three days afterwards, in order to escape the incessant search after him, he retired into another village. His enemies, however, were at hand, and having seized upon two youths, one of whom they forced by stripes to confess, they were by these lads conducted to his lodging. He might have saved himself by getting into another house; but he submitted, saying, "The will of the Lord be done." He therefore came down from his bed-chamber, and saluting his persecutors with a serene and cheerful countenance, he ordered a table to be set before them with provisions, invited them to partake, and only requested for himself one hour for prayer; after which he was set upon an ass, and conducted towards Smyrna. On the road he met Herod, a justice of the province, and his father, who were the principal instigators of the persecution. Herod took him up into his chariot, and strenuously endeavoured to undermine his constancy; but having failed in the attempt, he thrust him out of the chariot with so much violence and indignation, that his thigh was bruised by the fall. When at the place of execution, there came, as is said, a voice from heaven, saying, "Polycarp, be strong, and quit thyself like a man." When before the tribunal he was urged to swear by the genius of Cæsar. "Repent," said the proconsul, "and say with us, take away the impious." Upon this the martyr, looking round at the crowd with a severe and angry countenance, beckoned with his hand, and looking up to heaven, said with a sigh, in a very different tone from what they expected, "Take away the impious." At last, having confessed himself to be a Christian, the crier thrice proclaimed his confession, and the people shouted, "This is the great doctor of Asia, and the father of the Christians; this is the destroyer of our gods, who teaches men not to do sacrifice to, or worship, the deities." When the fire was prepared, Polycarp requested not to be nailed, as usual, but only tied to the stake; and after a short prayer, which he pronounced with a clear and audible voice, the executioner blew up the fire, which increasing to a mighty flame, "Behold a wonder seen by us, who were purposely reserved," says the relator, "that we might declare it to others; the flames, disposing themselves into the resemblance of an arch, like the sails of a ship swelled with the wind, gently encircled the body of the martyr, who stood all the while in the midst, not like roasted flesh, but like the gold or silver purified in the furnace, his body sending forth a delightful fragrance, which, like frankincense or some other costly spices, presented itself to our senses. The infidels, exasperated by the miracle, commanded a spearman to run him through with a sword; which he had no sooner done, than such a vast quantity of blood flowed from the wound as extinguished the fire, and then a dove was seen to fly from the wound, which some suppose to have been his soul, clothed in a visible shape at the time of its departure."[1] The Christians endeavoured to carry off his body entire, but were not allowed by the irenarch or justice, who commanded it to be burned to ashes. The bones, however, were gathered up, and decently interred by the Christians.

Thus died St Polycarp, on the seventh of the kalends of May, in the year 167. The amphitheatre on which he suffered was mostly remaining not many years ago; and his tomb, which is in a little chapel in the side of a mountain, on the south-east of the city, was solemnly visited by the Greeks on the festival day; whilst, for maintaining and repairing it, travellers were wont to throw a few aspers into an earthen pot which stands there for the purpose. He wrote some homilies and epistles, which are now lost, except that to the Philippians, which is a truly pious and Christian production, containing short and useful precepts and rules of life, which St Jerome informs us was even in his time read in the public assemblies of the Asiatic churches. It is singularly useful in proving the authenticity of the books of the New Testament; for he has cited several passages and expressions from St Matthew, St Luke, the Acts, St Paul's Epistles to the Philippians, Ephesians, Galatians, Corinthians, Romans, Thessalonians, Colossians, the first Epistle to Timothy, first Epistle of St John, and first Epistle of

---

[1] The miraculous part of this account is ridiculed by Dr Middleton in his Free Inquiry and Defence of it; but something is offered in its favour by Mr Jorton, who observes, "The circumstances are sufficient only to create a pause and a doubt." (*Remarks on Ecclesiastical History*, vol. i)

Peter; and makes particular mention of St Paul's Epistle to the Ephesians. Indeed the whole of this epistle consists of phrases and sentiments taken from the New Testament.

POLYCHORD, from the Greek πολυχορδος, a bow instrument resembling the double-bass, but smaller. It had ten strings, and a compass from C the second space in the bass clef, to C the third space in the treble clef. Its finger-board could be lengthened or shortened at pleasure, in order to tune the instrument. It was invented in 1799, by Hilmer, at Leipzig.

POLYCLETUS, a celebrated statuary and architect, who is said to have been a native of Sicyon, and a disciple of Ageladas. He was the fellow-disciple of Myron. But it seems doubtful whether he was born at Sicyon, since Plato, who was his contemporary, calls him in his dialogue entitled *Protagoras*, a native of Argos, and Maximus of Tyre expressly says that the statue of Juno was a work of Polycletus of Argos. He is not, however, to be confounded with another statuary of Argos, who lived at a later period. It is believed that he was born about 480 B. C., and was still alive 405 B. C., after the battle of Œgos-potamos, as Pausanias states that he executed one of the bronze tripods which the Spartans consecrated in the temple of Apollo at Amyclæ. By far the most celebrated of his statues was that of the Argive Juno, which is thought to have been executed about 416 B. C., eighteen years after the consecration of Jupiter of Olympia, and twenty or twenty-four years after that of the Minerva of the Parthenon. The statue of Juno was colossal, and seated on a golden throne, in a majestic attitude; the head, breast, arms, and feet, were of ivory, and the drapery of gold. She had a crown on her head, on which the artist had represented the Hours and Graces. In one hand she held a sceptre, with a cuckoo seated on it; in the other she bore a pomegranate. Her mantle was ornamented with vine branches, and her feet rested on the skin of a lion. Another celebrated statue was called *Canon*, or the Rule, because it was so perfect that it was looked upon as the model after which all others ought to be made. Galen says, that he composed a treatise on the proportions which constitute the harmony, and consequently the beauty of the human body, and that his statue was designed to illustrate his work. Winckelman suspects that this statue was also called Doryphorus, as Lysippus states that he formed his taste principally by studying it. The group called Canephoræ, two young girls carrying sacred baskets on their heads, formed part of the plunder of Verres, carried off from Messana in Sicily. It is believed that we have still a copy of his Diadumenos, in a young athlete attaching to his forehead a garland as the sign of victory, which is now in the Museo Borbonico at Naples. This Diadumenos was sold for about one hundred talents. As an architect, Polycletus is known to have constructed two buildings at Epidaurus, which are highly spoken of; the Tholus, a circular building, and a theatre, of which considerable remains are still to be seen. Varro thought that he had too much sameness in his statues; and Quintilian says that he never was able to represent the awful majesty of the gods, probably meaning such statues as the Jupiter and Minerva of Phidias. Amongst his pupils were Asopodorus, Aristides, Dinon, Athenodorus, and Pericletus the brother of Naucydes.

POLYCROTA, in the naval architecture of the ancients, a word used to express such of their galleys as had three, four, five, or more tiers of benches, seated at different heights. They were distinguished by this term from the *monocrota*, or those which had only single rows of oars. The number of rows of benches in the polycrote galleys has given occasion to some to suppose that those vessels were of such a height above the water as is scarcely credible. Commentators, however, are not at all agreed as to the construction of these vessels.

POLYDORE Virgil. See Virgil.

POLYDORUS, a son of Priam by Hecuba, or, according to others, by Laothe, the daughter of Altes, king of Pedasus. Being young and inexperienced when Troy was besieged by the Greeks, his father removed him to the court of Polymnestor, king of Thrace, to whose care he intrusted the greater part of his treasures, until his country should be freed from foreign invasion. On the death of Priam, Polymnestor made himself master of the riches which were in his possession; and to insure them the more, he murdered the young prince, and threw his body into the sea, where it was found by Hecuba. According to Virgil, his body was buried near the shore by his assassin; and there grew on his grave a myrtle, the boughs of which dropped blood, when Æneas, going to Italy, attempted to tear them from the tree.

POLYGAMIA (πολυς, *many*, and γαμος, *marriage*) is a term expressing an intercommunication of sexes, and is applied by Linnæus both to plants and to flowers. A polygamous plant is that which bears both hermaphrodite flowers, and male or female, or both.

POLYGAMY, a plurality of wives or husbands, in the possession of one man or woman at the same time.

Polygamy is so universally esteemed unlawful, and even unnatural, throughout Europe, and in all Christian countries, that we have generally reasoned upon this conviction. Both religion and reason appear at first sight at least to condemn it; and with this view of the subject mankind in general remain satisfied. But some bolder geniuses have taken the opposite side of the question, cast off the prejudices of education, and attempted to show that polygamy is not unlawful, but that it is just and necessary, and would be a public benefit. Such writers recur to the common subterfuge, of which every setter up of strange gods, and every conscientious troubler of the public peace, have artfully availed themselves, to silence the clamour of expostulation.

Dr Percival[1] has very justly observed, that the practice is brutal, destructive to friendship and moral sentiment, inconsistent with one great end of marriage (the education of children), and subversive of the natural rights of more than half of the species. Besides, it is injurious to population, and therefore can never be countenanced or allowed in a well-regulated state; for though the number of females in the world may considerably exceed the number of males, yet there are more men capable of propagating their species than women capable of bearing children; and it is a well-known fact, that Armenia, in which a plurality of wives is not allowed, abounds more with inhabitants than any other province of the Turkish empire.

Indeed it appears, that in several countries where it is allowed, the inhabitants do not take advantage of it. "The Europeans," says M. Niebuhr,[2] "are mistaken in thinking the state of marriage so different amongst the Mussulmans from what it is with Christian nations. I could not discern any such difference in Arabia. The women of that country seem to be as free and as happy as those of Europe possibly can be. Polygamy is permitted, indeed, amongst Mahommedans, and the delicacy of our ladies is shocked at this idea; but the Arabians rarely avail themselves of the privilege of marrying four lawful wives, and entertaining at the same time any number of female slaves. None but rich voluptuaries marry so many wives, and their conduct is blamed by all sober men. Men of sense, indeed, think this privilege rather troublesome than convenient. A husband is by law obliged to treat his wives suitably to their condition, and to dispense his favours amongst them with perfect equality; but these are duties not a little disagreeable to most Mussulmans; and such modes of luxury are too expensive to the Arabians, who are seldom in easy circumstances. I must, however, except one case; for it sometimes happens that a man marries a number of wives in the way of commercial speculation. I know a Mullah, in a town near the Euphrates, who had married four wives, and was supported by the profits of their labour."

---

[1] Phil. Trans. vol. lxvi. part i. p. 163.

[2] Niebuhr's Travels.

Selden has proved, in his *Uxor Hebraica*, that plurality of wives was allowed, not only amongst the Hebrews, but also amongst all other nations, and in all ages. It is true, the ancient Romans were more severe in their morals, and never practised it, though it was not forbidden amongst them; and Mark Antony is mentioned as the first who took the liberty of having two wives.

From that time it became pretty frequent in the empire till the reigns of Theodosius, Honorius, and Arcadius, who first prohibited it by express law in 393. After this the Emperor Valentinian, by an edict, permitted all the subjects of the empire, if they pleased, to marry several wives. Nor does it appear, from the ecclesiastical history of those times, that the bishops made any opposition to the introduction of polygamy. In effect, there are some even amongst the Christian casuists who do not look on polygamy as in itself criminal. Jurieu observes, that the prohibition of polygamy is a positive law, but from which a man may be exempted by sovereign necessity. Baillet adds, that the example of the patriarchs is a powerful argument in favour of polygamy. Of these arguments we shall speak hereafter.

It has been much disputed amongst the doctors of the civil law whether polygamy be adultery. In the Roman law it is denominated *stuprum*, and punished as such, that is, in some cases capitally. But a smaller punishment is more consistent with the Jewish law, in which the prohibition of adultery is perpetual, but that of polygamy temporary only.

Bernardus Ochinus, general of the order of Capucins, and afterwards a Protestant, published, about the middle of the sixteenth century, Dialogues in favour of Polygamy, which were answered by Theodore Beza. And about the close of the last century, an artful treatise was published at London in behalf of a plurality of wives, under the title of *Polygamia Triumphatrix*, the author of which assumes the name of *Theophilus Aletheus*, though his true name was *Lyserus*. He was a native of Saxony, and his work has been answered by several writers.

A new argument in favour of polygamy has been adduced by Mr Bruce, on the principle, that in some parts of the world the proportion of female children is much greater than that of the males. "From diligent inquiry," says he, "into the south and scripture part of Mesopotamia, Armenia, and Syria, from Mousul or Nineveh, to Aleppo and Antioch, I find the proportion to be fully two women to one man. There is indeed a fraction over, but it is not a considerable one. From Latikea, Laodicea *ad mare*, down the coast of Syria to Sidon, the number is nearly three, or two and three fourths, to one man. Through the Holy Land, the country called *Horan*, in the Isthmus of Suez, and the parts of the Delta unfrequented by strangers, it is something less than three. But from Suez to the Straits of Babelmandel, which contains the three Arabias, the proportion is fully four women to one man; which, I have reason to believe, holds as far as the line, and 30° beyond it. The imam of Sama was not an old man when I was in Arabia Felix in 1769; but he had eighty-eight children then alive, of whom fourteen only were sons. The priest of the Nile had seventy and odd children; of whom, as I remember, above fifty were daughters.

"It may be objected, that Dr Arbuthnot, in quoting the bills of mortality for twenty years, gave the most unexceptionable grounds for his opinion; and that my single exception of what happens in a foreign country, without further foundation, cannot be admitted as equivalent testimony; and I am ready to admit this objection, as there are no bills of mortality in any of these countries. I shall therefore say in what manner I attained the knowledge which I have just mentioned. Whenever I went into a town, village, or inhabited place, dwelt long in a mountain, or travelled journeys with any set of people, I always made it my business to inquire how many children they had, or their fathers, their next neighbours or acquaintance. I then asked my landlord at Sidon, suppose him a weaver, how many children he has had? He tells me how many sons and how many daughters. The next I ask is a tailor, a smith, &c., in short every man who is not a stranger, from whom I can get the proper information. I say, therefore, that a medium of both sexes, arising from three or four hundred families, indiscriminately taken, shall be the proportion in which one differs from the other; and this, I am confident, will give the result to be three women in 50° of the 90° under every meridian of the globe."

The same author corroborates his argument by supposing that Mahommed perceived this disproportion, and that upon it he founded his institution allowing one man to have four wives. "With this view he enacted, or rather revived, the law which gave liberty to every individual to marry four wives, each of whom was to be equal in rank and honour, without any preference but what the predilection of the husband gave her."

Having thus established, as he supposes, the necessity of polygamy in the East, Bruce proceeds to consider whether there is not some other reasons why it should not be practised in Britain further than the mere equality in numbers of the sexes to one another. This reason he finds in the difference between the constitutions of the Europeans and eastern nations. "Women in England," says he, "are capable of child-bearing at fourteen; let the other term be forty-eight, when they bear no more; thirty-four years therefore an English woman bears children. At the age of fourteen or fifteen they are objects of our love; they are endeared by bearing us children after that time; and none, I hope, will pretend, that at forty-eight and fifty an Englishwoman is not an agreeable companion. The Arab, on the other hand, if she begins to bear children at eleven, seldom or never has a child after twenty. The time, then, of her child-bearing is nine years; and four women, taken altogether, have then the term of thirty-six. So that the English woman that bears children for thirty-four years has only two years less than the term enjoyed by the four wives whom Mahommed has allowed; and if it be granted that an English wife may bear at fifty, the terms are equal. But there are other grievous differences. An Arabian girl at eleven years old, by her youth and beauty, is the object of man's desire: being an infant, however, in understanding, she is not a rational companion for him. A man marries there, say at twenty; and before he is thirty, his wife, improved as a companion, ceases to be the object of his desires and a mother of children: so that all the best and most vigorous of his days are spent with a woman he cannot love; and with her he would be destined to live forty or forty-five years, without comfort to himself by increase of family, or utility to the public. The reasons, then, against polygamy, which subsist in England, do not by any means subsist in Arabia; and that being the case, it would be unworthy of the wisdom of God, and an unevenness in his ways, which we shall never see, to subject two nations under such different circumstances absolutely to the same observances."

To all this argumentation, however, it may be replied, that whatever we may now suppose to be the constitution of nature in the warmer parts of the globe, it certainly was different at the beginning. We cannot, indeed, ascertain the exact position of the Garden of Eden; but it is with reason supposed not to have been far from the ancient seat of Babylon. In that country, therefore, where Mr Bruce contends that four women are necessary to the comfort of one man, it pleased God to grant only one to the first man; and that, too, when there was more occasion for population than ever there has been since, because the whole earth was to be peopled from a single pair. Matters were not altered at the Flood; for Noah had but one wife. And this is the very argument used by our Saviour himself when speaking of divorce without any sufficient cause, and then marrying another woman, which is a species of polygamy.

Again, with respect to the alleged multiplicity of females in the eastern part of the world, it is by no means probable that the calculations of Mr Bruce or any other person can be admitted in this case. History mentions no such thing in any nation; and considering the vast destruction amongst the male part of the human species more than that of the females, by war and other accidents, we may safely say, that if four women children were born for every single male, there would in such countries be five or six grown-up women for every man; a proportion which we may venture to affirm does not, and never did, exist anywhere in the world. That it was not so in former times, we can only judge from the particular examples recorded in history, and these are but few. We read in the Greek history, indeed, of the fifty daughters of Danaus; but these are matched by as many sons of another man. Job had only one wife, yet had seven sons and but three daughters. Jacob had two wives, who bore twelve sons, and only one daughter. Abraham had only one child by his first wife, and that was a son. By his second wife Keturah he had six sons; and, considering his advanced age at the time he married her, it is by no means probable that he could have twenty-four daughters; nay, if, as Mr Bruce tells us, the women in the eastern countries bear children only for nine years, it was impossible she could have so many. Gideon, who had many wives, had no fewer than seventy sons by these wives, and even his concubine had a son; so that if all these women had produced according to Mr Bruce's proportion, of nearly three females to one male, he must have had almost two hundred and eighty-four children; a more numerous family probably than any of which Mr Bruce's eastern acquaintance can boast.

With regard to the subject, however, it must be observed, that the procreation of male or female children depends in some degree on the health and vigour of the parents. It is by no means improbable, therefore, that the eastern voluptuaries, whose constitutions are debilitated by their excesses, may have many more female than male children born to them.

The boldest defence of polygamy that has appeared in modern times is that by the Rev. Mr Madan, who published a treatise artfully vindicating and strongly recommending it, under the title of Thelyphthora, or a Treatise on Female Ruin, in its Causes, Effects, Consequences, Prevention, and Remedy. Marriage, according to this writer, simply and wholly consists in the act of personal union, or *actus coitus*. Adultery, he says, is never used in the sacred writings but to denote the defilement of a betrothed or married woman, and to this sense he restricts the use of the term; so that a married man, in his opinion, is no adulterer, if his commerce with the sex be confined to single women, who are under no obligations by espousals or marriage to other men; but, on the other hand, the woman who should dare to have even but once an intrigue with any other man besides her husband, let him have as many wives as Solomon, would, *ipso facto*, be an adulteress, and ought, together with her gallant, to be punished with immediate death. This, he boldly says, is the law of God, and on this foundation he limits the privilege of polygamy to the man; in support of which he refers to the polygamous connections of the patriarchs and saints of the Old Testament, and infers the lawfulness of their practice from the blessings which attended it, and the laws which were instituted to regulate and superintend it. He contends for the lawfulness of Christians having, like the ancient Jews, more wives than one, and labours much to reconcile the genius of the evangelical dispensation with an arrangement of this sort. With this view he asserts, that there is not a single text in the New Testament that even hints at the criminality of polygamous connection; and he would infer from St Paul's direction, that bishops and deacons should have but one wife, that it was lawful for laymen to have more. Jesus Christ, he says, was not the giver of a new law; but the business of marriage, polygamy, and divorce, had been settled before his appearance in the world, by an authority which could not be revoked. Besides, this writer not only thinks polygamy lawful in a religious, but advantageous in a civil light, and highly politic in a domestic view.

In defence of his notion of marriage, which, he says, consists in the union of man and woman as one body, the effects of which in the sight of God no outward forms or ceremonies of man's invention can add to or detract from, he grounds his principal argument on the Hebrew words made use of in Genesis (ii. 24) to express the primitive institution of marriage, viz. רכק כאשתו, rendered by the Seventy *ϖροσκολληθησεται ϖρος τη’ γυναικα αὐτου*, which translation is adopted by the evangelist (Mat. xix. 5), with the omission only of the superfluous preposition (*ϖρος*) after the verb. Our translation, "shall cleave to his wife," does not, he says, convey the idea of the Hebrew, which is literally, as Montanus renders the words, "shall be joined or cemented *in* his woman, and they shall become (by this union) one flesh." But on this criticism it is well remarked, that both the Hebrew and Greek terms mean simply and literally attachment or adherence; and are evidently made use of in the sacred writings to express the whole scope of conjugal fidelity and duty, though he would restrain them to the grosser part of it.

With respect to the Mosaic law, for which Mr Madan is a warm advocate, it was certainly a local and temporary institution, adapted to the ends for which it was appointed, and admirably calculated, in its relation to marriage, to maintain and perpetuate the separation of the Jewish people from the Gentiles. In attempting to depreciate the outward forms of marriage, this writer would make his readers believe, that because none are explicitly described, therefore none existed; and consequently that they are the superfluous ordinances of human policy. But it is evident, from comparing Ruth (iv. 10, 13) with Tobit (vii. 13, 14), and from the case of Dinah, related in Genesis (xxxiv.), that some forms were deemed essential to an honourable marriage by the patriarchs and saints under the Old Testament, exclusive of the carnal knowledge of each other's persons. It is also evident in the case of the woman of Samaria, whose connection with a man not her husband is mentioned in John, iv., that something besides cohabitation is necessary to constitute marriage in the sight of God.

Having stated his notion of marriage, the same writer urges, in defence of polygamy, that, notwithstanding the seventh commandment, it was allowed by God himself, who made laws for the regulation of it, wrought miracles in support of it by making the barren woman fruitful, and declared the issue legitimate to all intents and purposes. God's allowance of polygamy is argued from Exodus, xxi. 10, and particularly from Deut. xxi. 15, which, he says, amounts to a demonstration. This passage, however, at the utmost, only presupposes that the practice might have existence amongst so hard-hearted and fickle a people as the Jews; and therefore wisely provides against some of its more unjust and pernicious consequences, such as tended to affect the rights and privileges of heirship. Laws enacted to regulate it cannot be fairly urged in proof of its lawfulness, on the author's own hypothesis; because laws were also made to regulate divorce, which Mr Madan condemns as absolutely unlawful, except in cases of adultery. Besides, it is more probable that the "hated wife" had been dismissed by a bill of divorcement, than that she was retained by her husband; and, moreover, it is not certain but that the two wives, so far from living with the same husband at the same time, might be dead; for the words may be rendered thus, "If there *should have been* to a man two wives," &c. The words expressing the original institution of marriage (Genesis, ii. 24), compared with Matthew (xix. 4, 5, 8), afford insuperable objections against Mr Madan's doctrine of polygamy.

If we appeal on this subject from the authority of Scripture to the writings of the earliest Fathers in the Christian church, there is not to be found the faintest trace of anything resembling a testimony to the lawfulness of polygamy; on the contrary, many passages occur in which the practice of it is strongly and explicitly condemned.

In a word, when we reflect that the primitive institution of marriage limited it to one man and one woman; that this institution was adhered to by Noah and his sons, amidst the degeneracy in which they lived, and in spite of the examples of polygamy which the accursed race of Cain had introduced;—when we consider how very few, comparatively speaking, were the examples of this practice amongst the faithful; how much it brought its own punishment along with it; and how dubious and equivocal those passages are in which it appears to have the sanction of divine approbation;—when to these reflections we add another, respecting the limited views and temporary nature of the more ancient dispensations and institutions of religion; how often the imperfections and even vices of the patriarchs and people of God, in the olden time, are recorded, without any express notification of their criminality; how much is said to be commanded, which our reverence for the holiness of God and his law will only suffer us to suppose were, for wise ends, permitted; how frequently the messengers of God adapted themselves to the genius of the people to whom they were sent, and the circumstances of the times in which they lived;—above all, when we consider the purity, equity, and benevolence of the Christian law; the explicit declarations of our Lord, and his apostle St Paul, respecting the institution of marriage, its design and limitation;—when we reflect, too, on the testimony of the most ancient fathers, who could not possibly be ignorant of the general and common practice of the apostolic church;—and, finally, when to these considerations we add those which are founded on justice to the female sex, and all the regulations of domestic economy and national policy,—we must wholly condemn the revival of polygamy, and thus bear our honest testimony against the leading design of this and all similar publications.

POLYGARS' TERRITORY. This is a district in the Southern Carnatic, and it is situated between the tenth and eleventh degrees of north latitude. To the north it is bounded by Trichinopoly, to the south by Marawas and Madura, to the east it has Tanjore and the sea, and to the west Dindigul. The Polygars, amongst whom this country is divided, are military chieftains, resembling the Zemindars of Bengal. Their estates are called Pallams. The country, before it was finally subdued by the British, having been long the scene of violence and disorder, where might was the rule of right, these Polygars were extremely averse to the British yoke, and defended their independence and their properties with resolution. They were, however, brought under subjection by the irresistible power of the British arms, and forced to yield to whatever terms were imposed upon them. Those who resisted the demand of tribute imposed on them, or showed signs of turbulence, were made prisoners, and deprived of their lands; others fled to the hills, where they made inroads on the lower country, collecting the tribute of their lands, or marauding and plundering the country. They have been now, however, mostly subdued, and the country has been restored to tranquillity, under the rule of the British.

POLYGLOTT, amongst divines and critics, denotes a Bible printed in several languages. See BIBLIOGRAPHY.

POLYGNOTUS, a famous painter of Thasos, flourished about 422 years before the Christian era, and was the son and scholar of Aglaophon. He adorned one of the public porticoes of Athens with his paintings, in which he had represented the most striking events of the Trojan war. The Athenians were so pleased with him, that they offered to reward his labours with whatever he pleased to accept; but he declined the offer; and the Amphictyonic council, which was composed of the representatives of the principal cities of Greece, ordered that Polygnotus should be maintained at the public expense wherever he went. Of the talents of Polygnotus, much honourable mention is made by many of the best authors of antiquity, as Aristotle and Plutarch, Dionysius of Halicarnassus, Pliny, and others. Pausanias speaks of his pictures of the events of the Trojan war, and, in his tenth book, introduces a long description of other pictures by the same artist, painted also from Homer, in the temple at Delphos. The passage, however, gives but a confused and imperfect idea of the painter's performance. How much the art is indebted to this ancient master, what grace and softness he gave to the human countenance, what embellishments he added to the female figure and dress, are much more happily described by Pliny. See also the article PAINTING.

POLYGON, in *Geometry*, a figure with many sides, or one the perimeter of which consists of more than four sides at least; such are the pentagon, hexagon, heptagon, and others.

POLYGRAPHY, POLYGRAPHIA, or *Polygraphice*, the art of writing in various unusual manners or ciphers; as also that of deciphering the same. The word is formed from the Greek πολυ, signifying *much*, and γραφη, *scriptura*, writing.

POLYHYMNIA, in the Pagan mythology, one of the nine muses, thus named from the Greek words πολυ, *much*, and μνεια, *memory*. She presided over history, or rather rhetoric, and is represented with a crown of pearls and a white robe; her right hand in action as if haranguing, and holding in her left a caduceus, or sceptre, to show her power.

POLYHEDRON, in *Geometry*, denotes a body or solid comprehended under many sides or planes.

POLYHEDRON, in *Optics*, is a multiplying glass or lens, consisting of several plane surfaces disposed into a convex form.

POLYMATHY denotes the knowledge of many arts and sciences. The word is derived from the Greek, πολυ, *multum*, and μανθανω, *disco*.

POLYNESIA.

olynesia.

aracte- tic dis- ction.

Polynesia is a name given by several early writers on geography, but first, we believe, by De Barros, to the numerous islands scattered over the Pacific Ocean, or, as it was usually called, the Great South Sea. It is the name which is now applied by most modern geographers to the *sixth* great division of the earth's surface; a division which will probably appear, on examination, less arbitrary than some others; for whether we consider it in a political, physical, or moral point of view, the separation from America on the one hand, and from Australasia and the Asiatic islands on the other, is marked by very strong and distinct features. A considerable portion of the two last, for instance, have, ages ago, been invaded and taken possession of by foreigners, and many of them have more recently been colonized by Europeans. No colonies have yet been planted in Polynesia, with the exception of that on one of the Ladrone Islands by Spain. Of late, however, many of these islands have been visited by European missionaries, for the purpose of spreading amongst the natives the light of the gospel; and in many cases their efforts have been so far successful that they have established permanent settlements in these islands, and have instructed the natives, not only in the doctrines of the Christian religion, but in all the mechanical arts and other improvements of civilized society. The inhabitants have no political connection with any of the other divisions of the earth, and little or none exists between any two of its groups or separate islands, each being governed by its own chiefs, and confining its friendships or hostilities to some neighbouring group or island.

ysically isidered.

Physically considered, the line of separation is almost as distinct as their political seclusion. If a line be drawn in a south-easterly direction along the eastern extremity of the Philippine Islands, Mindanao, Papua or New Guinea, New Ireland, and Solomon's Archipelago, and from thence continued southerly along the eastern shores of the New Hebrides and New Zealand, this line will mark with sufficient precision the separation of the Asiatic islands (mostly to the northward of the equator) and Australasia (to the southward of the equator) from Polynesia. Besides, the geological structure of the islands which constitute the last-mentioned divisions is, generally speaking, essentially different, consisting chiefly of lofty mountains of primary or secondary formation, partaking of the same structure as those on the continent of Asia, with which some of them indeed may probably have once been connected, their rugged sides presenting as it were a broken barrier to the Great Pacific; whereas Polynesia exhibits a series of low, flat islands, scarcely rising above the level of the sea, which, with the exception of a few of the larger groups of volcanic formation, are the labours of minute sea animals, and are usually distinguished by the name of Coral Islands or Reefs.

rally sidered.

In a moral point of view, the distinctive character of the Polynesians is as strongly marked as the physical structure of the islands which they inhabit. In the Eastern Archipelago, or the Asiatic islands, and in Australasia, two distinct races of men have been traced, the *black* and the *brown*. In the archipelago, and more particularly in the Philippine Islands, a few individual families of the negro race were discovered by the early European visitors; in New Guinea and the Papuan Islands the whole population appears to consist of this race. They differ in some respects from the negroes of the western coast of Africa, resembling rather those which are found on the eastern coast, particularly in the hair, which is strongly twisted into small tufts, and very different from that of the negro of Guinea.

Polynesia.

Natives of Polynesia.

None of these negroes have been discovered on any of the islands of Polynesia, all the inhabitants being of the *brown* race, and evidently derived from the same common stock to which the Tartars, the Chinese, the Japanese, and the Malays, owe their origin. In this opinion Sir William Jones, Dr Buchanan, Dr Hunter, Mr Marsden, and Sir Stamford Raffles, unanimously concur. This race, modified, of course, by the circumstances of climate, occupations, and habits, may thus be described:—Their persons short, squat, and robust; their lower limbs large and heavy; their arms fleshy; hands and feet small; face somewhat of a lozenge shape, the forehead and chin rather sharpened, but broad across the cheek-bones, which are high, and the cheeks hollow; the eyes black, small, narrow, and placed obliquely in the head, the external angle being the highest; nose broad, but not flat, and nostrils open and circular; mouth rather wide; hair harsh, lank, and quite black.

Language.

Dispersed as the Polynesians are, and rarely and purely accidental as any communication between distant islands must be, it is perfectly certain that the different dialects spoken, from the shores of India and Africa to those of America, are the derivatives of one common language, which, according to Marsden, still forms the primitive portion of the Malay language, mixed as it now is with Sanscrit and Arabic. "The Malayan," says this learned and accurate writer, "is a branch or dialect of the widely extended language prevailing throughout the islands of the archipelago to which it gives name, and those of the South Sea, comprehending, between Madagascar on the one side and Easter Island on the other, both inclusive, the space of full two hundred degrees of longitude. This consideration alone is sufficient to give it claim to the highest degree of antiquity, and to originality, as far as that term can be applied."

Religion.

Not less remarkable is the general accordance of the Polynesians in manners, superstitions, and religious observances. The conversion of the Malays of the archipelago to Mahommedanism has obliterated nearly their ancient faith, but enough still remains on some of the Asiatic islands, and still more on the Asiatic continent, to trace the source whence the Polynesians have derived their notions and practices on matters of this kind.

General view of the islands.

These preliminary observations on the physical form, features, language, and religion of the Polynesians, are made with a view to assert their common origin, and may be taken as a general description of the natives of the various groups of islands which are scattered over the surface of the vast Pacific Ocean. These groups are exceedingly different in their extent, both as to number and size, as well as in their composition. Sometimes single islands are met with, surrounded by rocky reefs. These islands and reefs are dispersed, as already observed, over the whole of the Pacific Ocean, but chiefly between the thirtieth degree of northern and the thirtieth degree of southern latitude. The following classification will be found to embrace the greater part of those islands which are comprehended under the geographical division Polynesia:

Classification of the islands.

In the Northern Hemisphere.

1. The Marian or Ladrone Islands.
2. The Carolinas, including the Pellew Islands.
3. The Sandwich Islands.
4. The numerous reefs and coral islands scattered over the Pacific in both hemispheres.

In the Southern Hemisphere.

1. The Friendly Islands, including the group of the Tonga Islands.

2. The Navigators' Islands.
3. The Society Islands.
4. The Georgian Islands, including Otaheite or Tahiti, and the great range extending as far as Pitcairn's Island.
5. The Marquesas.
6. Easter Island.

IN THE NORTHERN HEMISPHERE.

Ladrones.

1. The Ladrone Islands were first discovered by Magelhaens on the 6th of March 1521. This name, by which they are generally known, was given to them by the Spaniards on account of the thievish disposition of the natives. They also called them Islas de los Velos Latinas, in reference to the sails of their canoes. By some they were called Los Jardinas (the Gardens), and by others Dosprazeres (the Delightful Islands); and when missionaries were first sent thither in 1668, under the patronage of Mary-Anne of Austria, queen of Philip, they took the name of Las Marianas, in honour of that lady. They consist of four larger and several smaller islands. The former are called Saypan, Tinian, Zarpan or Rosa, and Aguigan, or rather Guahan. Saypan has a lofty peak, evidently volcanic, but the rest are of a moderate height, and are surrounded by rocks of coral formation. They lie between latitude 13° and 15½° N., longitude about 144° E.

Visited by Magelhaens.

On approaching these islands, Magelhaens perceived that they were inhabited, and the natives presently came off to the ships with cocoa-nuts, yams, and rice. They were stout, well-made people, of a pale-yellow complexion, long black hair, and their teeth dyed red or black; an apron of the bark of a tree was their only covering, a lance pointed with a fish-bone their only weapon. Their boats had lateen or shoulder of mutton sails, with outriggers to prevent their upsetting, and they sailed with great swiftness. The captain-general was so delighted with the appearance of the country, that he intended to refresh his crew amongst them; but such numbers of the inhabitants flocked on board his ships, and were so addicted to thieving, that, being under the necessity of driving them away by force, hostilities ensued, and several of the natives were killed. Magelhaens had one of his boats stolen, which so exasperated him that he landed with ninety of his people, set fire to their houses, which were of wood, and carried off all the provisions he could find.

By Loyosa.

The expedition of Loyosa, commanded, after his death, by Sebastian del Cano, and at his decease by Alonzo de Salazar, touched at the Ladrone Islands in 1526, and being received in the most friendly manner, procured water and provisions in plenty for the sickly squadron. To the great surprise of the Spaniards, a countryman of theirs, named Gonzalo de Vigo, came to them from one of the islands, having deserted from one of the ships of Magelhaens; two others, he said, had deserted at the same time, but were put to death by the natives. They found no quadrupeds on the island, but plenty of excellent fruits, fish, and rice. The only birds were turtle-doves, of which the islanders appeared to be so fond, that they kept them in cages, and taught them to speak.

By Lopez de Legaspe.

In 1565, the Ladrone Islands were again visited by Lopez de Legaspe. Whilst the ships were yet two leagues from the shore, the natives came off in their canoes, but kept at a distance from the ships. The general put knives and other articles on a plank, and floated it off, and the natives showed fruits, patting their bellies, and pointing to the shore, to induce the Spaniards to land. This they did the following day on the island of Guahan, and exchanged bits of iron for provisions; but notwithstanding the regulations made by Legaspe in order to prevent quarrels, skirmishes took place, and one of the seamen, who had strolled into the woods, being found murdered, the Spaniards landed in force, set fire to their houses and canoes, wounded several of the natives, and hung upon the spot three wounded prisoners.

No kind of animal was found on the island, nor would the natives taste any other animal food except fish. "But that which caused most admiration," says Friar Gaspar, "was, that they would drink salt water, and were such expert swimmers, and passed so much of their time in the water, that, as among other animals, some are amphibious, in like manner it seemed as if these people were in their nature amphibious."

Visited b Cavendis

In 1588, our countryman Candish or Cavendish came in sight of the Ladrones, and sailed along the coast of Guahan, from which a number of canoes came off with fruits and vegetables, which were exchanged for pieces of iron; but the natives became so troublesome, that, in order to get rid of them, Cavendish ordered muskets to be fired at them.

By Olivie Van Noort

In 1600, Olivier Van Noort made the Ladrone Islands, and stopped near Guahan for two days, from which island above two hundred canoes came off to the ships with fish, fruits, and rice, to exchange for iron; and fowls are also mentioned, for the first time, in this voyage. In the same year, the Santa Margarita, a Spanish ship, having lost her captain and many of her crew by sickness, anchored off Saypan, and was taken possession of by the natives, who killed some of the crew, and took others of them on shore, where they were kindly treated, and such as survived were afterwards taken off by a Spanish ship which had been sent for the purpose.

By Spilber gen and th Nassau fleet.

In 1616, Spilbergen made the Ladrone Islands, and stopped two days to traffic with the natives for provisions of fruit, fowls, and fish, in exchange for bits of iron. In 1625, the fleet under Prince Maurice of Nassau refreshed at Guahan, and were supplied by a hundred and fifty canoes, with immense quantities of cocoa-nuts, yams, bananas, rice, and fowls, which were of infinite service, as the scurvy had made such havoc among the crews, that in some of the ships they had scarcely strength enough to manage the sails.

Of the Spa nish Jesuits.

In the year 1668, the Spaniards established a mission on the island Guahan, consisting of P. Servitores and five other fathers, with several lay-assistants, most of them natives of the Philippine Islands, and well acquainted with the Tagul language, the same as that spoken by the natives of the Ladrone Islands. For some time the chiefs of the islands behaved with great kindness to the Jesuits, and gave them ground for building a church. From this seat of the mission the fathers spread themselves amongst the other islands, where they were received with equal kindness. In short, P. Servitores says, that in the first year they had baptized more than thirteen thousand islanders, and instructed twenty thousand, in the eleven islands which they had visited. As usual, however, the imprudent zeal of the missionaries ruined their cause, by shocking the prejudices of the natives. These simple people took it into their heads that, as an infant had died shortly after being baptized, its death had been occasioned in consequence of that ceremony; and such was the terror of mothers on seeing a missionary approach, that they seized their children and ran off with them into the woods. This opinion gathered ground from the eagerness of the Jesuits to get hold of infants for the purpose of baptizing them, and more than one of these holy fathers fell martyrs to their imprudent zeal. Several murders ensued; and, as the Spaniards had taken care to strengthen the mission with a body of troops well armed, with the obvious intention of taking possession of the Ladrones as an important outpost to the Philippine Islands, after a great number of the natives had been put to death, the rest submitted to the yoke of the Spaniards; though most of the missionaries suffered in the contest, and last of all Servitores, who was killed by the man to whom he had been the greatest benefactor, because the missionary insisted on baptizing his child. Thus, at the age of forty-five, this pious and good man, for such he certainly was, fell by the hand of an assassin, after having, as we are told, "established the faith in thirteen islands, founded eight churches, established three seminaries for the instruction of youth, and baptized nearly fifty thousand of the islanders." From this time constant revolts and massacres ensued, and the most inhuman cruelties were inflicted on the unhappy islanders; so that, in 1681, the island of Guahan, which, on the first landing of the Spaniards, counted forty thousand inhabitants (some accounts make them more), had become so completely depopulated, that it was found necessary to bring inhabitants from the northern islands to cultivate the soil.

Visited by he buca-ieers.

In the year 1685, the ship of John Eaton, the bucaneer, touched at Guahan, the crew of which quarrelled with the natives, and killed some of them. Having satisfied the Spanish governor that it was done in their own defence, "he gave us toleration," says Cowley in his narrative, "to kill them all if we could."..."We took four of these infidels prisoners," continues the narrator, "and brought them on board, binding their hands behind them; but they had not been long there, when three of them leaped overboard into the sea, swimming away from the ship, with their hands tied behind them. However, we sent the boat after them, and found a strong man, at the first blow, could not penetrate their skins with a cutlass; one of them had received, in my judgment, forty shots in his body before he died; and the last of the three that was killed had swam a good English mile first, not only with his hands behind him, as before, but also with his arms pinioned." We are told by the late Captain Burney, that it is stated in Cowley's manuscript in the British Museum, that "the boat coming up with them, our carpenter, being a strong man, thought with his sword to cut off the head of one of them, but he struck two blows before he could fetch blood."

y Dam-ier.

In 1686, Dampier touched at Guahan, and states the number of natives not to exceed a hundred. He gives a particular description of their "flying proas," with their outriggers, which, he says, "sail the best of any boats in the world; that he tried the swiftness of one by his log, and that she ran twelve knots out before the half-minute glass was half out." "I believe," says Dampier, "she would run twenty-four miles an hour." Woodes Rogers, who visited the Ladrones in 1710, states it as his opinion that one of these proas would sail at the rate of twenty miles an hour.

y Anson.

In the month of August 1742, Commodore Anson anchored before the island of Tinian. It was deserted, but cattle to the number of at least ten thousand, hogs and fowls, were running about wild. Cocoa-nuts in innumerable quantities, bread-fruit, oranges, limes, water-melons, and other tropical fruits, were in the greatest abundance. The island swarmed with rats, and the flies, mosquitoes, and ticks or bugs, were very troublesome; but it was a paradise to the crew of the Centurion, in the horrible state of scurvy in which they arrived. Though now deserted, Tinian, on the arrival of the Spaniards, is said to have contained thirty thousand inhabitants. Ruins of buildings, consisting of pyramidal pillars of considerable dimensions, were met with in all parts of the island.

y Byron.

Commodore Byron anchored in the year 1765 before Tinian, and found the island overgrown with large trees and underwood, amongst which were most of the tropical fruits. He complains bitterly of the bad anchorage, brackish water, and venomous insects, from which they suffered so severely, that "we were afraid," he says, "to lie down in our beds;" and though his crew recovered fast from the scurvy, he lost two by fevers, being the first deaths in his ship since leaving England. "I am indeed of opinion," says the commodore, "that this is one of the most unhealthy spots in the world, at least during the season in which we were here;" yet it was in the same month that it had been visited by the Centurion.

By Kotzebue.

The latest account of these islands is that of Lieutenant Kotzebue, who visited Guahan in 1817. No canoes nor proas, nor happy islanders, greeted his approach; the whole race of natives had long been extirpated. "We looked," he says, "in vain for a canoe or a man on the shore; and it almost seemed as if we were off an uninhabited island. The sight of this lovely country deeply affected me. Formerly these fertile valleys were the abode of a nation, who passed their days in tranquil happiness; now only the beautiful palm groves remained to overshadow their graves; a death-like silence everywhere prevailed." Soon, however, a person appeared from the Spanish governor, and piloted the ship into the harbour; and after this, Kotzebue proceeded to the town of Agana, situated upon a beautiful plain, some hundred paces from the shore, in the midst of fine palm groves, some of the houses being built of coral rock, others of bamboo. It has a church and a convent, and two fortresses, one to protect the town from the seawards, and the other to keep the Indians in awe. The town contains about 200 houses, and 1500 inhabitants, who derive their origin from Mexico and the Philippines. The population of the island is about five thousand souls. "There is but one man and his wife," says Kotzebue, "on the whole island of the original stock; with the death of these two people, the race of the old Ladrones will be totally extinguished." "The present race," says Chamisso, "no longer know the sea, are no mariners, no swimmers; they have ceased to build boats. They now scarcely hollow out, without skill, the trunks of trees to fish within the breakers." All the other islands to the north of Guahan are entirely uninhabited, and overrun with wild cattle, hogs, and goats, which afford a supply to the American vessels trading to the Sandwich Islands and the north-west coast of America. Indeed it is said that some of these people have been allowed to settle themselves in Agrigan, on condition of acknowledging their allegiance to Spain, and that they are peopling the island by kidnapping the natives of the Sandwich Islands.

Carolinas.

2. The *Carolinas*, or Caroline Islands.—In 1686, a Spanish ship, being near the meridian of the Ladrones, fell in with an island, which her commander, Don Francisco Lazeano, named La Carolina, in honour of the king of Spain, Carlos II. This island has given the name to a very extensive chain spreading over a space of not less than six degrees of latitude and twenty-five degrees of longitude, the western extremity being the group of the Palaos or Pellew Islands, in latitude 7° north, longitude 135° east, and the easternmost island, that of Hogolen, in latitude 9° north, longitude 155° east. The whole group, as far as is known, which, however, is very imperfectly, consists of at least a hundred and fifty separate islands, and may be nearly twice as many, besides various coral reefs with islets upon them. Yet, numerous as they are, being somewhat out of the direct and usual route of the Spaniards in their voyages from South America to the Philippines, they had the good fortune to escape any intimate connection with them; a connection which has proved equally baneful to others, whether established by the cross or the sword, by their professions of friendship or avowals of hostility. Gobien, the historian of the desolating progress of the Spaniards in the Ladrones, says that Quiroga, the governor, made search for the island of Carolina, "wishing to extend the faith to its infidel inhabitants, and, for that purpose, sent some soldiers, and with them the chanionis (or chief), Don Alonzo Soon; but after a fruitless search, and much pains, they returned without finding the object of their research."

Some of these islands, however, and especially those towards the western extremity of the group, had been seen by various navigators long before that of Carolina was noticed and named by Lazeano. The Portuguese, Da Rocha, fell in with islands in 9° or 10° north latitude, in 1526, which he named Sequeira, after his pilot; and, in 1628, Saavedra, a Spaniard, in his passage to the Philippines, discovered islands in latitude 11°, which he named Los Reyes. In 1579, our countryman Drake saw some islands, to which he gave the name of the Islands of Thieves, which, from his description, have been supposed to be the Pellew Islands. In 1595, one of the islands, in about 6° north, was seen by Mendana; but two proas full of people, driven by the violence of the wind from a group of islands in the east, as far as Samal, roused the attention of the College of Jesuits at Manilla, who made several unsuccessful attempts to establish missions on those islands, which the wrecked natives described to consist of thirty-two in number. In the year 1710, the two fathers, Duberron and Cortel, embarked in the San Trinidad, with a crew of eighty-six men, to establish themselves on the Pellew Islands. They landed on Sonsorol, with the quartermaster and ensign of the troops, in all sixteen persons; but the ship being driven off by the current, made for another of the islands, called Panloque, at the supposed distance of fifty leagues from the Sonsorolles. On approaching the island, several boats came off, and some of the Palaos people swam from them to the ship, and coming on board, attempted to steal whatever they could lay their hands on. In consequence of this, they were ordered away; and having reached their boats, began to shoot arrows at the ship, which were answered by a discharge of musketry. The ship now returned to the Sonsorolles to inquire after the two missionaries and the boat; but the strong winds and currents would not suffer them to anchor, nor could they see or hear anything of their companions, though they stood in towards the shore within cannon shot. A storm coming on, left them no alternative except "to return to Manilla, with the sorrowful news of what had happened." What became of the missionaries was never ascertained. The following year, however, P. Serano departed from Manilla, in a ship fitted out for the purpose, in search of the two fathers and their companions; but she foundered three days after she departed from Manilla, and every person on board perished, except one Spaniard and two Indians, who brought back the melancholy intelligence.

In the *Lettres Edifiantes et Curieuses* is a letter and chart from P. Juan Antonio Cantova, a missionary at Guahan, addressed to the king of Spain's confessor in 1722, in which is given a more particular account of the Carolinas than any which had before or has since been published. It states that, in the preceding year, a bark, with eleven men, seven women, and six children, arrived on the east side of Guahan; and that, two days after, another canoe, with four men, one woman, and child, came to the opposite side of the island. The two parties, on being brought together, recognised each other with great joy. It appeared they had been dispersed by a gale of wind, and driven about for twenty days, without knowing where they were. Cantova thus describes them: They wore a garment open at the sides, but covering the shoulders and breast, and extending down to the knees. The women had a piece of cloth round the waist, falling, like a petticoat, to the middle of the leg. Their hair was curly, the nose large, the eyes large and penetrating, and the beards of the men moderately thick. Some had the pure colour of the Indians; others were apparently of a mixed breed between Spaniards and Indians, and others between a negro and an Indian. Cantova succeeded in learning their language, and obtained from them the following particulars respecting their islands.

The Carolinas are divided into five provinces. Beginning at the east, the first is named Cittac; the principal island, Hogolen, is much larger than Guahan; its inhabitants are negroes, mulattoes, and whites. There are eighteen principal islands in this province, besides a multitude of smaller ones. The second province consists of about twenty-six islands, of which Ulee and Lamurree are the principal ones. The third province consists of a group of islands, of which Feis is the principal, being very populous and fertile; but the chief of the group resides at Mogmog, and all the proas which approach this island lower their sails in token of respect to this chief. Of the fourth province, Yap is the principal island, about a hundred and twenty miles in circuit, very populous, and fruitful. The fifth province is the most westerly, and is named Panleu (the Palaos, or Pellew Islands), of which there are seven principal islands. It is remarkable that the inhabitants of these islands so far differ from the Carolinians in general, and from the account given of them in the romance of Mr Keats, drawn up by that ingenious gentleman from the documents furnished by Captain Wilson, that they are represented as a most barbarous race, both men and women going entirely naked, and feeding on human flesh. We are told by the naturalist of Kotzebue's expedition, that a Spaniard, who had lived nine months on the Pellew Islands, and whom they met with at Cavité, gave him a horrible account of the natives; that they were wholly without shame, that husbands lend their wives for a mere trifle, that the women are without modesty, and that they certainly eat human flesh; a great part of which was confirmed by a native of the Carolinas, who had been at the Pellew Islands.

Cantova further learned from the islanders, that to the eastward were a great number of other islands, the inhabitants of which pay adoration to the shark; that most of them are negroes, and of savage dispositions. It is supposed that Cantova returned with these islanders in the year 1722, though no account of any such voyage is on record; but in 1731 he embarked for the islands of the third province, in company with another father, of the name of Walter, from which the former never returned. The latter, however, returned to procure certain articles of which they stood in need, was driven to the Philippines, re-embarked in 1732, and was wrecked. Walter again embarked in May 1733, along with forty-four persons. On the ninth day they approached the island, and fired cannon to inform Cantova of their arrival, but no boat appeared. Standing within a musket-shot of the shore, they observed that their former habitation had disappeared, as well as the cross which had been erected near the sea-shore. Four small canoes at length approached the vessel, bringing cocoanuts. On inquiring after Cantova and his companions, the islanders were evidently embarrassed, and said they were gone to Yap. Being fearful, by their manner, that the good father had fallen by the hands of the barbarians, and willing to be satisfied on this head, they seized one of the islanders, upon which the rest swam ashore. After the strongest assurances that no harm should be done to him, provided he would tell the truth, he confessed that shortly after the departure of Walter, the natives put the Father Cantova to death, and all his companions, fourteen in number. Cantova, it seemed, from this man's account, went, with his interpreter and two soldiers, to the island Mogmog, to baptize, whilst the rest remained at Falalep. He had scarcely set his foot on shore when he was surrounded and pierced through and through with lances, the natives crying out that he was come to take away the old law, and give them a new one. They gave his body a decent burial, but the bodies of his companions were put into a canoe, which was then turned adrift upon the ocean. The same people then went over to the island of Falalep, and put to death the remainder of the companions of Cantova.

Since that time, little or no information has been procured respecting the Carolinas, with the exception of that which is contained in the narrative of Mr Keats, from the materials of Captain Wilson, who, when commander of the Antelope packet, in the service of the East India Company, was wrecked on Oroolong, one of the Pellew Islands. Whatever their general character may be, the crew of the Antelope found them a friendly, hospitable, and humane people. They were stout, well made, rather above the middle size, and their colour approaching to a deep brown; their hair long, some wearing it loose, and others turned up. The men were entirely naked; the women contented themselves with two little aprons or fringes, made of the fibres of the cocoa-nut husk, about ten inches deep and seven wide, one of which was worn before, and the other behind. Both sexes were tattooed; the men had one ear perforated, the women both, and they wore beads, tortoise-shell, or leaves, as suited their fancy; the cartilage of the nose was also bored, and a little sprig or blossom of some plant was generally stuck in the hole; their teeth were dyed black by a paste prepared of certain herbs, which, it is pretended, caused severe sickness for five days, the time required to complete the operation.

Their productions, and the manners of the natives.

Fish and cocoa-nuts are the chief articles of food, but the islands afford an abundant supply of yams, plantains, oranges, lemons, bread-fruit, carambola, and the areca-nut; the sugar-cane grew wild. No quadruped, except rats, was found on the islands; of birds, the pigeon was the most abundant, and the domestic fowl ran wild in the woods. The natives were wholly unacquainted with the use of salt. Their usual beverage consisted of the milk of the cocoa-nut. Their houses were of bamboo and plank, raised upon stones from the ground. The husk of the cocoa-nut supplied them with nets and cordage, and the tortoise-shell with hooks to catch fish. Their knives were made of mother-of-pearl, shells, or split bamboo; the cocoa-nut served them for cups, the plaintain leaf for plates, and the fibres of this plant for mats to sleep on. Their weapons were spears of wood, darts, and slings. Their boats were canoes made of the trunks of large trees, and some of them sufficiently capacious to hold from twenty to thirty persons. In the day-time they seemed to live as much in the water as on shore, and both sexes were admirable swimmers. The women mixed freely with the other sex, and their conduct was not strictly inquired into by their husbands. They seemed to have little sense of any religious duties, except in the ceremonies attending the burial of the dead, which takes place in spots set apart for that purpose, and with great solemnity; but they have some faint notion that the soul survives the body. Their graves very much resembled those in a country church-yard of England, some having earth heaped up in the same manner, and others covered with flat tombstones, and protected by fences of wicker-work.

The larger of the Pellew Islands are of a moderate height, rising into beautiful hills, well clothed with forest trees. The natural history still remains unknown, but being about the same parallel and of the same formation with the numerous group visited by Kotzebue, the plants and animals are in all probability much the same. The smaller islands are the productions of the coral-making animals, with which the larger are also surrounded to a great distance from their shores.

Sandwich Islands.

3. *The Sandwich Islands.*—This fine group of islands in the Northern Pacific had the good fortune to escape the visits of the old navigators, and the discovery of them was reserved for Captain Cook, who first touched at them in the year 1778, and lost his valuable life there in 1779. M. Fleurieu, in his introduction to Marchand's Voyage, is disposed to dispute this claim, and to assign the first discovery of these islands to Mendana, for no other reason but that it appears he passed at no great distance from Owyhee, but without seeing it, on his return voyage in 1568; and because he finds an island named Mesa laid down on the nineteenth parallel of latitude, on the obscure and unauthenticated chart of Galion de Manille. It is almost unnecessary to add, that the name by which they are now known was given to them by Captain Cook, in honour of the Earl of Sandwich, under whose naval administration geography was enriched with many important discoveries.

Extent and population.

According to Captain King, the group consists of eleven islands. But the missionaries only enumerate ten; and they reduce the population below the estimate of former voyagers. The following is the estimated length, breadth, and superficial contents of these islands. The names are given according to the orthography of the missionaries.

	Length in Miles.	Breadth in Miles.	Square Miles.	Population.
Hawaii (Owyhee)	97	78	4000	85,000
Maui (Mowhee)	48	29	600	...
Tahurawa	11	8	60	...
Ranai	17	9	100	...
Morokai (Morotoi)	40	7	170	...
Oahu, or Woahoo	46	23	520	20,000
Tanai	33	28	520	...
Niihau	20	7	80	...
Taura Morokini	Little else than barren rocks.			

The missionaries estimate the whole population at 130,000. Others raised it to 400,000. We have no data for any accurate calculation. But if Oahu and Owyhee contain, as the missionaries state, 105,000, their estimate of 130,000 for the whole must be under-stated. They are situated between latitude 18. 54. north (the south point of Owyhee), and 22. 2. north (the latitude of Woahoo), and between the longitude 199. 36. (the small island of Tahurawa), and 205. 6. (the eastern extremity of Owyhee).

The island of Owyhee is described as rising majestically in grand unbroken lines from the ocean, and forming three several mountain peaks, on two of which lies snow for the greater part of the year. They are as under:

	Height.
Mouna Roa (Great Mountain)	2482 toises.
Mouna Kuah (Little Mountain)	2180
Mouna Wororai	1687

These measurements, as given by Kotzebue, agree within a few toises with those of Marchand. The whole group is of volcanic origin, and on the summit of Mouna Wororai is an immense crater. The last eruption from the side of this mountain took place in 1801. The chain of mountains runs from the north-west point of Owyhee, over the islands Mowhee, Morotoi, and Woahoo. On Mowhee is a peak as high nearly as that of Wororai, but the latter is the only volcano in a state of activity.

Description.

These islands, though volcanic, are surrounded by coral reefs, and the plains next the sea, which are raised only a few feet above it, were once of the same description, and covered with water. These plains are generally naked and sunburnt, but the valleys amongst the mountains are beautifully picturesque and fertile, and the sides of the hills are covered with magnificent forests. The most fertile and best cultivated of the group is Woahoo, on which is the safe and capacious harbour of Hana-rura, protected by a coral reef, through a break of which lies the entrance to it. In one of the mountains a diamond mine was supposed to exist, but the products turned out to be only quartz crystals. In the Pearl River of this island oysters have been found containing pearls, but none of much value.

Natural productions.

Amongst the indigenous plants mentioned by Chamisso, the naturalist of Kotzebue's expedition, are the acacia, metrosideros, pandanus, santalum, aleurites, dracœna, amomium, curcuma, tacca. The families of rubiaceæ, contortæ, and urticæ, predominate. From the latter, as well as from the paper mulberry (*Broussonetia papyrifera*), are made their cordage and cloths. The acacia tree, used for their boats and canvass, grows only in mountains, which is the case also with the sandal-wood, the principal article of export from the islands.

Cultivation. The plants mostly in use for domestic purposes are the banana-tree, the cocoa-nut tree, the bread-fruit, sugar-cane, yam, batatos, and the taro-root (*Arum esculentum*), of indigenous growth; besides which have been introduced the tobacco plant, the melon, and water-melon, rice, and the vine, the last of which will unquestionably thrive well on the sides of the volcanic mountains; also cucumbers, cabbages, beans, and the cloth plant, together with a few oranges and pine-apples. The cultivation of the taro-root has the greatest share of attention bestowed on it; and, in fact, it constitutes a considerable portion of the food of the people. The fields or ponds in which this root is planted are enclosed with stones in the form of regular squares, from a hundred to two hundred feet each side; these squares are connected by sluices to convey the water from one to the other, pretty much in the same manner that the Chinese manage their rice-fields. "I have seen," says Kotzebue, "whole mountains covered with such fields, through which the water gradually flowed; each sluice formed a small cascade, which ran through avenues of sugar-cane, or banana, into the next pond, and afforded an extremely picturesque prospect."

Distillation of spirits. A convict from New South Wales has taught the people of these islands the art of distilling ardent spirits from sugar-cane, and a plant called the tee-root (the *Dracœna terminalis*). And, as every chief has now his still, it is probable that the use of the pernicious *kava* will give way to that of the almost equally pernicious spirituous liquors. This *kava* is the liquor or juice of a root of the pepper tribe (*Piper methysticum*), chewed and spit out into a large bowl, and then diluted with water, and this exquisite beverage is prepared for the sole use of the king and the nobles, the women being prohibited from tasting it. The baneful effects of this liquor have been noticed by most voyagers; the bodies of those who swallow it are, in process of time, covered with a white scurf, their eyes become red and inflamed, their limbs emaciated, and their whole frame trembling and paralytic.

Quadrupeds. When Captain Cook first discovered these islands, the only quadrupeds upon them were hogs, dogs, and rats. They have now horses, asses, horned cattle, many of them running wild in the mountains, and goats. Hogs are exceedingly abundant. "They are so large," says Kotzebue, "that the whole crew could not eat one in two days;" and the flavour, from being fed on sugar-cane, is very superior to European pork. Fowls, ducks, and geese, are equally abundant.

Progressive civilization. The Sandwich Islands, though last discovered, have been more frequently visited by Europeans and Americans, and particularly by the latter, than any other group of islands in the whole range of Polynesia; and they have made greater advances in civilization than any other of the Polynesian islands. They were indebted for this superiority to the enterprising character of their monarch, Tamehameha I., who seems fully to have appreciated the advantages of European improvements. When Captain Vancouver visited these islands in 1792, the king being desirous of having a vessel of European construction, this able navigator laid down the keel of one, which was speedily finished. Ten or twelve years after this, when Mr Turnbull visited the islands, he had a naval force of twenty vessels or upwards, from twenty-ty-five to fifty tons, which traded amongst the islands. He had built a house for himself, after the European manner, with windows of glass, and he imitated the English in his dress. By means of English and American seamen and artificers, some of whom deserted from ships touching there, and others obtained regular permission to remain on the islands, most of the trades exercised in Europe were partially introduced into the Sandwich Islands.

The attention of Tamehameha, though he was a decided reformer, was chiefly directed to the improvement of his dress and dwelling, to the building of forts for the protection of his islands, and to the training of his soldiers in the European mode of discipline. But he was not equally solicitous for intellectual improvements; and he adhered most tenaciously to the faith and to all the customs of his forefathers. In a visit to the Morai, pointing to the large wooden statues, he said to Kotzebue, "These are our gods, whom I worship. Whether I do right or wrong I do not know, but I follow my faith, which cannot be wicked, as it commands me never to do wrong." Such sentiments do honour to the savage; and the man who entertains them is capable of being instructed in better things.

During his reign, also, the women continued to be degraded and despised; and, notwithstanding the frequent intercourse with strangers, and the improvements which undoubtedly have been introduced, the sex do not appear to have gained a single step in the estimation of the men, or lost any part of their grossness of behaviour since they were first visited by Captain Cook. That "offensively conspicuous wantonness," which Vancouver deplores, and to which he found no parallel in the whole of Polynesia, appears to have suffered no abatement. When Campbell, the seaman, was on the island of Woahoo, the king's brother died, on which occasion, as part of the general mourning, a public prostitution of the women took place. The captain of a ship then in the harbour remonstrated with the king, who coolly observed, it was their custom, and he could not prevent it. The women, too, it seems, are more addicted to drinking than the men. The governor of Woahoo invited Kotzebue and his officers to witness a dance of the natives, at which he was not present, but sent an apology to say, that his lady was so drunk that he could not leave her. The women are also great smokers of tobacco, and continue it sometimes till they fall down senseless.

Though the women are so far degraded that they cannot eat in the same house with their lords and masters, and must not taste at all of certain articles, yet if the latter be sick, they must howl and make lamentations, tear their hair, lacerate their cheeks; and if he should die (provided he be a Jerrie, Eree, or noble), the favourite wife must die with him. The victims, both men and women, who are to be sacrificed at the death of Tamehameha, are well known; nor is it concealed even from themselves, and they glory in the distinction. "I have myself," says Kotzebue, "seen one of the devoted victims in Woahoo, a man who was always cheerful and happy." On the death of the king, these people will be led bound into the royal Morai (temple and burning place), where, after the prescribed ceremonies, they will suffer death at the hands of the priests. The ancient system of idolatry was calculated to operate on the fears of its votaries. "Its requisitions," says one of the missionary writers,[1] "were severe, and its rites cruel and bloody. Grotesque and horrid wooden figures, animals, and the bones of chiefs, were the objects of worship. Human sacrifices were offered whenever a temple was to be dedicated, or a chief was sick, or a war was to be undertaken, and these occasions were frequent. The apprehensions which the people have of a future state were undefined and fearful. The lower orders expected to be slowly devoured by evil spirits, or to dwell with the gods in burning mountains. The several professions, such as that of the fisherman, the tiller of the ground, and the builder of canoes and houses, had each their presiding deities. Household gods are also kept, which the natives worshipped in their habitations; the volcanoes had moreover a superintending power. One merciful provision, however, had existed from time immemorial, and that was sacred enclosures, places of refuge, into which those who fled from war or from any violent pursuer might enter and there be safe."

---

[1] Evangelical Magazine, No. 37, January 1826, p. 30.

To violate the sanctity of the Morai is one of the greatest crimes of which a man can be guilty. Campbell was present at the execution of a man who had committed this offence, in getting drunk and running out of the Morai during *tabboo* time. He was taken back to the Morai, where his eyes were put out; in this state he remained two days, when he was strangled and his body exposed before the image of Etooah, or Eatooah, the principal deity, who, according to their belief, is the creator of the universe, and who afterwards destroyed it by an inundation that covered the whole earth except Mouna Roa, on the top of which one single pair had the good fortune to save themselves, from whom the present race of men, that is, the Sandwich Islanders, sprung.

That singular superstition by which the king, the nobles, and the priests, under the name of *tabboo*, have contrived to render sacred and inviolable whatever they may wish to appropriate to their own use, and which is in universal operation through the whole of Polynesia, is practised to a great extent in the Sandwich Islands. By means of it, a whole people are contented to be robbed of their property, and to suffer any privations that may be imposed on them, without murmuring. When their houses are *tabbooed* they dare not enter them; when their *taro-roots* or their hogs are tabbooed, they surrender them without a struggle; but in return, it must be owned, they are not scrupulous in appropriating to themselves whatever is not *tabbooed*.

Amongst the customs which they inveterately retain, is that of *tattooing* the body; this operation being also universal amongst the islanders of the Pacific. The hands and arms of the women, in particular, are marked with peculiar elegance of figure, and many of the women have the tip of the tongue tattooed. Contrary, however, to the common practice of the islanders, they do not paint their bodies, nor wear ornaments of any kind in the ears; but the women decorate their hair, which is cut short, with wreaths of flowers, and wear necklaces, bracelets, and anklets of shells, coral, and other substances. The common dress of the men is the *maro*, a piece of cloth about a foot wide, which, passing between the legs, is tied round the waist; that of the women is a short petticoat, reaching about half-way down the thigh. The chiefs, on days of ceremony, and on particular occasions, wear cloaks made of the most beautiful feathers, with an elegantly-shaped helmet to correspond. They are ambitious, however, to appear in the dress of Europeans, to enable them to do which, great quantities of old laced coats are carried out to the Sandwich Islands as articles of commerce.

The character of these islanders, like that of all savages in their natural state, is stained with every degrading vice. The missionaries who were stationed in the island, and who had the best opportunities of estimating the dispositions of the natives, describe them as lamentably debased; being in the continual practice of theft, treachery, drunkenness, gross licentiousness, and infanticide, and strangers to every social and domestic virtue. Polygamy is the common custom; and murder by poison is believed by the natives to be very frequent. Great improvements have, however, been effected by the instructions of the missionaries, who have persevered in this, as in the other islands, with an enthusiasm that has at length been crowned with success, and has laid the foundation of a great moral change in the condition of these barbarous islanders. The system of idolatry, so far as it was connected with the government, was abolished by Rhio-Rhio, or Tamehameha II., the son and successor of Tamehameha I., who laid the foundation of social improvement amongst his subjects. This took place in 1819, before any Christian missionaries came into his dominions. He was induced to adopt this policy from various causes, namely, a desire to improve the condition of his wives, who were subject, along with all other females, to many inconveniences, from the operation of the *tabboo* already explained. *2dly*, Several foreigners and intelligent chiefs advised the change; and the report of what had been done by Pomare, king of Otaheite, in the Georgian Islands, had great weight with him. Some disturbances took place in consequence of the abolition of idolatry; but the insurgents were defeated, and peace was restored. In 1820, missionaries were, after some difficulty, allowed to settle, some at Kairua, but the greater number at Honororu, on the island of Oahu or Woahoo. They had to encounter difficulties, moral as well as physical, in their ignorance of a rude unwritten language, which they mastered, however, by perseverance, and constructed an alphabet, and finally a grammar and spelling-book, which was in great demand amongst the natives. In the year 1822 they had made such proficiency that Mr Ellis began to preach in the native language; and six missionary stations were established, at each of which a church was erected, and worship regularly celebrated on the Sunday. In 1824, the king and queen of the Sandwich Islands embarked, amidst the sighs and tears of their subjects, on a voyage to Great Britain, where they died the same year. Their bodies, with their surviving attendants, were brought to the Sandwich Islands in the Blonde frigate, under the command of Lord Byron. Kamkeoli, the brother of the king, was unanimously acknowledged as his successor, under whose protection the missionaries continued their labours, often under great discouragements, in establishing schools, planting churches, training native teachers and missionaries, and in instructing the people in industry and the mechanical arts. The church at Oahu was resorted to by great numbers. It contains only seven hundred, and two thousand were often assembled without doors. According to late accounts, sixty-three schools, containing 1583 scholars, and under the superintendence of native teachers, had been visited; besides others in the vicinity of Honororu. Spelling-books to the amount of thirteen thousand had been distributed amongst the people. Amongst those who paid attention to the instructions of the missionaries, numbers made an open profession of the Christian faith; and amongst all a stricter morality prevailed. They became more humane, more industrious and honest; the females no longer, as formerly, resorted for prostitution to British ships; they adopted a different dress, after the European fashion, and many were baptized. This sudden change, however, appears to have been owing as much to the love of novelty as to the influence of a purer faith; and, accordingly, it has been found in this, as in the other islands, that the gloss of novelty having worn off, many of the wholesome restraints imposed upon their unbridled passions have been thrown off, and they have relapsed into their former barbarous and profligate habits. Still the seeds of civilization have been scattered far and wide, and in due time, we may be assured, they will bear fruit. The people may relapse to a certain degree, but they will never sink to their former state of barbarism. There is no doubt, in short, that since the missionaries have established themselves in these islands, and our ships of war have frequented them, a great change has taken place in the habits and moral character of the natives. "I was glad," says Captain Bruce of the Imogene, "that, at the spot where the intrepid navigator Cook met his untimely end, his memory is cherished with the greatest veneration, and that the prevalence of Christianity is now general throughout the island." The same observation will apply to the Society Islands, and indeed to all those where the missionaries have established themselves. The odious part of the habits and manners of the people is fast disappearing.

Coral islands and reefs.

4. *Coral Islands and Reefs.*—The number and position of the multitude of low islands, sometimes found in groups, and sometimes solitary, are by no means yet ascertained; but,

from the various tracts of ships, it is known that the whole of that part of the Pacific lying between the equator and the tenth degree of north latitude, and from the Pellew Islands to 180° longitude, being at least forty-five degrees of longitude, is completely studded with low coral islands and reefs in countless numbers, some of them inhabited, and others not; and in different stages, from the circular reef, with islets rising upon it like the beads of a necklace, with a lagoon in the centre, to the complete consolidation into one firm island. About the tenth parallel, and proceeding easterly from the Carolinas, we have Button, Tindall, Watt's, and Gilbert's Islands; and about the longitude 175° east, a whole group, extending to the southward of the equator, named on some charts "Lord Mulgrave's Range," on others "Scarborough's Range;" some of the individual islands of which are Smith's, Allen's, Gillespie's, Toulmin's, Hopper's, Chatham's, Calvert's, Robertson's, Arrowsmith's, Daniel's, Marshall's, Pott's, near to which are Kingmill's Group and Byron's Island, all of coral formation.

Various accounts have been given by Cook, Forster, Flinders, and others, of the progressive formation of these low specks of land, with which the Pacific is studded; but the best and most satisfactory is that by Kotzebue and the naturalist Chamisso. They not only saw the Lord Mulgrave's chain of islands, which extend from 1° to 12° north, of which Gilbert's Islands form the northern and Marshall's Island the southern extremity, but they discovered and examined minutely many other groups and detached islands. Between the eighth and tenth degrees of north latitude, and between longitude 188. 48. and 190. 46., they encountered no less than six distinct groups, to which they understood the natives applied the name of Radack; and they learned that to the westward were nine other groups, and three detached islands, called Ralick, besides four groups to the southward. The Radack chain probably includes those which were seen by Captain Marshall in 1788, and to which he gave the name of Chatham and Calvert Islands, though Kruzenstern thinks that these are the same as the Ralick chain. It is not of much importance in a geographical point of view, whatever it might be for the benefit of navigation.

The small size of Kotzebue's vessel gave him the advantage of sailing through the openings in the circular reefs, and of examining the lagoons within them. From his account, it would seem that the coral-making animals do not commence their labours at the very depth of the ocean, as has been supposed, but on rocky shoals, the summits, in all probability, of submarine mountains, round which they lay the foundation of their extraordinary fibres, forming an united chain, irregular in shape, but generally approaching, more or less, to a circle. The greatest depth at which they are able to derive a sufficient degree of light and heat for their operations has not yet been ascertained; but we know that marine animals have been drawn up in a living state from the depth of a thousand fathoms, and from a temperature very little above that of the freezing point. The outer edge of the reef exposed to the surf of the sea is the first that shows itself above the water; in process of time it becomes indurated, breaks, and crumbles, by the action of the sea, and at length forms a sort of barrier, within the sloping sides of which the living animals are seen carrying on their operations. Those observed by Chamisso were the *Tubipora musica*, the *Millepora cærulea, obstichopora, actimas*, and various kinds of the polypus. He found the living branches of the *lythophytes* generally attached to the dead stems; many of the latter, however, crumbled into sand, which, accumulating on the inner declivity, constitutes no inconsiderable part of the surface of the new islands that rise out of this reef, and are gradually united into one island, having in its centre a salt-water lake, that alternately grows up by a silent and slow progress, till what was at first a chain of islets, has become one connected mass of land. The progress towards a state fit for the habitation of man has been well described by Chamisso.

"As soon as it has reached such a height that it remains almost dry at low water, at the time of ebb, the corals leave off building higher; sea-shells, fragments of coral, sea-hedgehog shells, and their broken-off prickles, are united by the burning sun, through the medium of the cementing calcareous sand, which has arisen from the pulverization of the above-mentioned shells into one whole or solid stone, which, strengthened by the continual throwing up of new materials, gradually increases in thickness, till it at last becomes so high that it is covered only during some seasons of the year by the high tides. The heat of the sun so penetrates the mass of stone when it is dry, that it splits in many places, and breaks off in flakes. These flakes, so separated, are raised one upon another by the waves at the time of high water. The always active surf throws blocks of coral (frequently of a fathom in length, and three or four feet thick) and shells of marine animals between and upon the foundation stones; after this, the calcareous sand lies undisturbed, and offers to the seeds of trees and plants, cast upon it by the waves, a soil upon which they rapidly grow, to overshadow its dazzling white surface. Entire trunks of trees, which are carried by the rivers from other countries and islands, find here, at length, a resting place, after their long wanderings; with these come some small animals, such as lizards and insects, as the first inhabitants. Even before the trees form a wood, the real sea-birds nestle there; strayed land-birds take refuge in the bushes; and, at a much later period, when the work has been long since completed, man also appears, builds his hut on the fruitful soil formed by the corruption of the leaves of the trees, and calls himself lord and proprietor of this new creation."

IN THE SOUTHERN HEMISPHERE.

Friendly Islands.

1. *The Friendly Islands.*—The Friendly Islands, amongst which may also be included the Feejee Islands, were first discovered by Abel Jansen Tasman in 1643, to three of which he gave the names of Amsterdam, Middleburgh, and Rotterdam. The first of these islands is that which was afterwards visited by Captain Cook, and described by him under the name of Tongataboo; more properly, as we since learn from Mr Mariner, *Tonga*, the annexed word *Tabboo*, so extensively used throughout Polynesia, being expressive only of its sacred character. From the inhabitants of this island Tasman received yams, cocoa-nuts, bananas, hogs, and fowls, in exchange for iron, nails, beads, and pieces of linen. They had also plenty of sugar-canes. Women as well as men swam off to the ship, and it was observed that all the elder dames had the little finger of both hands cut off, but the young women had not. They wore round the middle a covering of mat-work, which reached down to their knees; the rest of the body naked. None of the men would taste wine, and they were ignorant of the use of tobacco; they had no arms of any kind, which led Tasman to conclude that they lived in perpetual peace and friendship.

Tasman next touched at Ammomooka, or, as he called it, Amsterdam Island, in the hope of meeting with better water than on the first, where it was bad and scanty. On landing, they perceived some sixty or seventy persons sitting quietly on the shore, who had no arms of any kind, and appeared to be a harmless and peaceable people. There were, besides, many women and children, the former clothed like those on Amsterdam Island; but they were of a larger size, and as strong in their bodies and limbs as the men. The party was shown to a piece of fresh water not a mile from the shore, about a quarter of a mile in circumference, and about a musket-shot from the north side of the island, where there was a good sandy bay. Here they watered their ships, and received abundance of provisions, the same in kind as those of the other island. The inhabitants are described as being great thieves, but very friendly. They have large vessels with masts, sails, and outriggers, as well as canoes, and on going into the interior of the island it was observed that all their plantations were laid out in neat and regular order. "There was not," says Captain Cook, "an inch of waste ground; the roads occupied no more space than was absolutely necessary; the fences did not take up above four inches each, and even this was not wholly lost, for in many were planted some useful trees or plants. It was everywhere the same; change of place altered not the scene; nature, assisted by a little art, nowhere appears in more splendour than here." The missionaries, too, in 1797, found these islands in as high a state of cultivation and beauty as they appeared to Tasman and to Cook.

Revolution the go- ernment.

A woful difference in their peaceable habits, according to Mr Mariner, has taken place since the visits of these Europeans. In 1799 a revolution took place, and from that time bloody wars and most savage slaughter have desolated these beautiful islands. They were first commenced, as it would appear, by a most atrocious savage, in whom the kingly power was vested, who not only practised the most barbarous cruelties on his subjects, but seized upon the sacred or ecclesiastical power, which had always, as in Japan, been kept separate from the secular arm. The sacred spell being thus broken, which rested solely on public opinion, a complete revolution followed, and from that hour these once happy islands have been the scene of slaughter, famine, and every species of horror and misery. We must not, however, give implicit credit to all that has been stated by Dr Martin, the writer of Mariner's account of these islands, but rather consider it as a romantic exaggeration of facts and descriptions, similar to that of the Pellew Islands by Mr Keats. There are shades of difference merely between the inhabitants of these and of the neighbouring islands.

In 1833, missionaries were detached from Tahiti, the centre of all the settlements in the South Seas, to these islands. They experienced on their arrival difficulties and discouragements from the barbarous inhabitants; but by perseverance they expect to obtain a footing, and to introduce amongst them the blessings of civilization, as well as into the other islands among these seas.

The Harvey Islands[1] are situated between 19° and 22° south latitude, and 160° west longitude, and are between 500 and 600 miles south-west by west from Otaheite or Tahiti. They consist of the island Manaia or Mangeca, a small island containing only 1000 or 1500 inhabitants; Rarotonga, a much larger island, containing from 6000 to 7000 inhabitants; Aitutake; Mantii or Mante; Mitiaro, a very small island; Atui. Three of these islands are not laid down in any chart. The missionaries, when they first visited them, met with every discouragement, and could scarcely preserve themselves and their wives from the violence of the king. Two missionaries, however, visited these islands in 1823, and two native teachers were also left in 1824; and in the course of two months they had made a hundred and twenty converts. In 1825, these islands were visited by missionaries from this country, and it was found that great progress had been made in civilizing and instructing the inhabitants. Many had learned to read; whilst their idolatrous and cruel practices, such as infanticide, had been abolished. More decent clothing had been adopted by the women, who were no longer so ready to offer themselves for prostitution to crews of foreign vessels when they arrived. An attempt that was made to plant the Christian religion in the Feejee Islands had failed. But a vessel from New South Wales having touched at Lageba in 1829 or 1830, the captain had a friendly conversation with the chief, who requested that a missionary might be sent. A teacher, accordingly, set sail from Otaheite, and landed on these islands in 1830.

In 1830, two missionary teachers were left on the Friendly Islands, in which, though distinct, the Feejee Islands have been included. They were kindly received, but were informed by the king that he could not embrace Christianity until after he had consulted with all the chiefs of the other islands; that they had been erecting a most extensive Morai, about seventy-six feet in height, all of stone, which had given way three times, and which misfortune they ascribed to the power of the new God. One chief, converted by native missionaries, expressed his adherence to the Christian faith, amidst the scoffs, jeers, and even threats of his countrymen.

Navigators' Islands.

2. *Navigators' Islands.*—To the north-east of the Feejee, Tonga, or Friendly Islands, are situated the Bauman or Navigators' Islands. The first name was given to them after Captain Bauman, of the Teinhoven, by Jacob Roggewein, by whom they were discovered, in 1722; and the latter name was conferred by Bougainville, who passed them in 1768. La Pérouse likewise visited these islands, and is of opinion that they are not the same as Bauman's Islands, because their geographical position does not agree with that assigned to them by Roggewein. Burney, however, has no doubt that they are identical, the only difference being in their supposed longitude, which, in the time of Roggewein, was frequently set down erroneously by several degrees.

Description of the islands and natives.

These islands form an archipelago, consisting, according to La Pérouse, of ten in number, of which Maouna, Oyolava, and Pola are the largest and most beautiful. The parallel of 14° south latitude, and the meridian of 190°, pass through the centre of the group. According to the missionaries, these islands, which they also designate as the Samoa Islands, are eight in number, four in the windward group, and four in the leeward group, two much larger than Otaheite, two others noble islands, and the remaining four small, though full of inhabitants. To the largest they gave the appellation of Savai and Upola. They are said by La Pérouse to be volcanic, but surrounded by coral reefs. Roggewein describes the hills and valleys as affording a delightful prospect. The natives came off in boats neatly made and carved, bringing fish, cocoa-nuts, and plantains. They are said to have white skins, but tanned by the sun, to be gentle in their manners towards each other, lively and good-humoured; their bodies were neither painted nor marked, and they were clothed from the waist downwards; the cultivated grounds were all enclosed; and, in short, they are described by the writer of Roggewein's voyage as the most civilized and honest people they had met with amongst the islands of the South Sea. We may conclude, indeed, from his account, that they were equally well cultivated, and the inhabitants equally mild and peaceable, with those of the Friendly Islands.

Very different, however, is the account given of them by La Pérouse. Ferocious in the highest degree, he describes them as utterly destitute of gratitude and every good moral feeling; that a look of disdain is stamped on all their countenances; and that they are eternally fighting with each other, so that their bodies are covered with scars occasioned by the blows of clubs. Tall in stature, their limbs are of colossal proportions; and their bodies are tattooed to such a degree as to make them appear clothed, though they have only a girdle of sea-weeds round their loins, which reaches to the knee. The size of the women corresponds with that of the men, and their whole behaviour is represented as highly indecent and disgusting. They had no desire for iron, preferring their own adzes and other tools made of basalt. Their huts were made with great nicety, and all their wood-work was highly polished and carved. Their matting and cloth were exceedingly beautiful; the latter woven with thread made from the nettle, and a species of flax. The sails of their boats or canoes were made of this cloth. The islands are so intersected with creeks that they travel from place to place almost universally in canoes, which have outriggers to prevent them from upsetting.

---

[1] Missionary Chronicle for September 1826.

Fertility.

All the islands were clothed with trees up to the very summit of the hills, many of them laden with fruit. The villages are ranged along the margin of the streams which fall from the mountains, and are built in the midst of groves of cocoa, banana, guava, and other fruit-trees common to the South Sea Islands. The woods abound with wild pigeons and turtle-doves, which are tamed by the natives, and kept about their houses in flocks of many hundreds. Sugar-cane grows abundantly and without culture. Their animals are pigs, dogs, and the domestic fowl; these, and the fish, which they catch with great expertness, afford them an abundant supply of food. These islands were visited for the first time by the missionaries in 1830, who placed eight teachers on the large island of Savai. They were kindly received by the chiefs; and they considered that their prospects of civilizing these islands, and of reclaiming them from idolatry, were very favourable. A fierce war was waging at the time the missionaries landed, between the islands of Upola and Savai, which they interposed with their counsels to appease; and the chiefs promised that they would terminate it, and come and learn from the missionary teachers the word of God. These islands were visited, in 1834, by five missionaries from Otaheite. They were kindly received by the natives, who still continued to express the strongest desire for their instructions, and several of whom had made an open profession of the Christian faith. Four additional missionaries arrived in these islands at the close of the year 1835; and as their reception was friendly, they had commenced their labours amidst a population of 50,000, with every prospect of success.

Society Islands.

3. *Society Islands.*—The first account of these islands is given in the voyage of Jacob Roggewein, who touched at Ulietea in the year 1722; at least it is conjectured by Burney, on probable grounds, that the Verquickking or Recreation Island of that navigator is the same. On sending a boat on shore, the inhabitants assembled on the beach, and advanced into the water armed with lances to oppose their landing. The Hollanders fired upon them, and having dispersed them, landed on the beach, and the inhabitants returned in a friendly manner, and brought them cocoa-nuts and other articles of food. The Hollanders then advanced up a valley towards the mountains; but some thousands of the natives coming out of the glens and crevices, made signs to them to return. The Hollanders, however, paid no regard, but proceeded, upon which showers of stones were hurled at them, by which some were killed and others wounded. These volleys were answered by a discharge of musketry, which killed many of the islanders, who, nevertheless, continued the action, and finally drove the Dutchmen into their boats. Many of the latter subsequently died of the wounds they had received, in consequence of the bad state of their constitutions, being severely affected with the scurvy.

Description.

Captain Cook visited these islands in 1769, and again in 1777. They consist of six in number (besides small coral islets), the names of which are Ulietea and Otaha (both encompassed by the same coral reef), Huaheine, Bolabola, Tubai, and Maurua. They extend from about 16° to 17° south latitude, and from 151° to 152° west longitude. The climate, the productions, and the inhabitants, resemble so nearly those of Otaheite, that the same description will apply to both. The surfaces of all the islands are uneven and hilly, but not mountainous; and the hills are finely wooded. The inhabitants, like those of the Navigators' Islands, are generally of a larger stature than the Otaheitans. The late Sir Joseph Banks measured one of the natives of Huaheine, and found him to be six feet three inches and a half in height; and the women are described as generally more handsome and somewhat fairer than those of Otaheite. Bolabola differs from the rest of the islands by having a lofty double-peaked mountain near its centre, apparently volcanic. In Ulietea there is a large Morai, in which a number of jaw-bones are kept as trophies of war. The coral reefs which everywhere surround these islands form numerous safe and commodious harbours for shipping, and refreshments of hogs, fowls, plantains, cocoa-nuts, and yams, are generally to be had in great abundance.

In these islands, the missionaries, though long disappointed, and though their lives were frequently endangered by the contests and revolutions which agitated the country, at last succeeded, by their perseverance and intrepidity, in establishing stations in Huaheine, Ulietea or Raiatea, Taha or Otaha, and Borabora or Bolabola. It was about the year 1817 that a missionary, Williams, landed in Raiatea, where he has laboured ever since with perseverance and fidelity. The inhabitants of Taha are strongly attached to their ancient idolatrous worship. They opposed the introduction of Christianity, and even went to war with the king of Raiatea because he had agreed to renounce idolatry. But they were worsted in the contest, and the king was taken prisoner. Instead, however, of being put to death, as formerly, with cruel tortures, he was humanely treated, which made such a deep impression on his mind that he embraced Christianity; and in 1824, in Raiatea, 178 children had been baptized, and 140 taught to read. In Huaheine, missionary stations were also established, and the preachers laboured with success in the conversion of the natives. In 1830, at the public examination of the schools, 370 children were present, all very neatly dressed in European cloth; and many of the chiefs and parents were present on the occasion. The same success attended the efforts of the missionaries in Borabora. But the progress of this moral reformation experienced some serious interruption. The indolent dispositions of the people, from habit or from the heat of the climate, indisposed them to industry; and, from the introduction of spirits, both in Raiatea, Borabora, Huaheine, and in the other islands, they relapsed into all their gross excesses. One of the old chiefs, who had favoured the introduction of the missionaries, having died, his successor, who had resided at Huaheine, was much addicted to intemperance; and a person from Botany Bay having brought ashore a cask of spirits, the slumbering appetite was rekindled, and the people, encouraged by their chief, gave way to almost universal dissipation; and though the introduction of spirits had been prohibited before, they now began to erect stills for distillation in various quarters. The missionaries did all they could to repress this flood of dissipation; and they succeeded at last in putting a stop for a time to the use of spirits. In Borabora and Maupiti, the chief, Mai, desirous of having more than a single wife, left the missionary settlement, attended by a great part of his people; and at their new settlement they abandoned the profession of the Christian religion, and commenced the distillation of ardent spirits. The missionaries, however, do not relax in their labours; though the encouragements are not so great as could be desired, yet they hazard everything, even life itself, in the hope of spreading their doctrines among distant nations. They so far prevailed, that the people agreed to give up the use of spirits; and a law was enacted, inflicting a heavy penalty on any one who should be found engaged in distillation.

Georgian Islands.

4. *The Georgian Islands, including Otaheite, &c.*—Otaheite is the chief island of this vast group, which extends

over fifteen degrees of longitude, in the direction of south-east. The extreme point is Pitcairn's Island, lately become interesting on account of the discovery of the descendants of the mutineer Christian and some of his associates. The natives of this vast chain of islands, and particularly of Otaheite, may probably be considered as the most civilized, but, at the same time, the most sensual people in all Polynesia. It was first discovered by Quiros in 1606, and received from him the name of Sagittaria. The natives received the strangers with great kindness, gave them cocoa-nuts and other fruits, and a general interchange of civilities and presents soon took place. This good understanding remained uninterrupted, and the Spaniards, for once, left the island without having quarrelled with the inhabitants. In their zeal, however, they committed an act which, if discovered, might have been attended with unpleasant circumstances. The place at which they first landed was uninhabited, but in passing through a wood they discovered a Morai, in which they concluded " the enemy of mankind resided;" and, under this impression, cut down a tree, which they formed into a cross, and planted in the midst of the sacred building.

In 1765, Commodore Byron discovered two low islands to the northward of Otaheite, which, in honour of his majesty, he named George's Islands, one of which, afterwards visited by Cook, is called Tiookea. The natives of these islands were very dark coloured, robust, and apparently ferocious; and their bodies were marked with the figure of a fish.

In 1767, Captain Wallis touched at Otaheite, and went through the ceremony of taking possession of the island in the name of his sovereign; but the flag was removed by the natives in the night. Various squabbles occurred between the seamen and the natives, who, however, behaved on the whole with great kindness and hospitality. Most of the quarrels were owing to the licentious intercourse of the seamen with the native women. In 1768, M. de Bougainville visited Otaheite, and was most hospitably received; in return for which several murders were committed by the French seamen. Captain (then Lieutenant) Cook anchored in Matavai Bay in April 1769. It is from this and his several subsequent visits, together with a missionary voyage in the ship Duff, commanded by Captain Wilson, 1796–1798, that Otaheite is so well known to us.

taheite.

The island consists of two peninsulas, connected by a low isthmus, about three miles in width, covered with brushwood. The larger, Otaheite Nove, is about ninety miles in circumference, and nearly circular; the smaller, Tiaraboo, is about thirty miles; the whole nearly surrounded by a low belt of land, from a furlong to a mile in width, which is prolonged by a gradual rise to the valleys, which run up to the foot of the lofty central mountain. These valleys and their intermediate ridges are beautiful, clothed with a great variety of trees to their very summits; in the valleys are mostly met with clear streams of water, which, in the rainy season, become mountain-torrents. The island, being surrounded with coral reefs, is dangerous to approach, and the only safe harbour is that of Matavai, on the northern side, in latitude 17. 30. south, longitude 149. 13. west. This too is not free from danger from December to March. The climate is delightful, the thermometer seldom rising above 80° in summer, and ranging from 62° to 72° in winter.

oduc-
ns.

The island is so fertile as to produce everything in abundance, and without toil, for the sustenance of man. The bread-fruit is here superior to that which grows on the other islands. The fruit affords them a most nutritive food, either for present use, or made into a paste called *mahie*, which will keep till the following season; the trunk supplies them with timber for their buildings and canoes. It exudes a gum, which serves for pitch; and from the inner bark is manufactured a substantial cloth. They reckon no less than thirty varieties of this most useful tree, which, with the different exposures to the trade-winds, and the difference of elevation above the sea, afford to the natives a bread-fruit harvest at almost all seasons of the year. The cocoa-nut, next to the bread-fruit, supplies them with meat, drink, cloth, and oil. Of plantains, they reckon fifteen different sorts. Yams and sweet potatoes, taro-root of different kinds, and various other edible roots and fruits, are most abundantly produced; to which our missionaries have added the pine-apple, the grape, and various culinary vegetables of Europe; but the natural and spontaneous productions of the soil, and the consequent indolence of the people, are unfavourable to their success.

Animals.

The animals found on the island are hogs, dogs, and rats. Several attempts have been made to introduce the horse, and horned cattle, sheep, and goats, but without success. The latter are so disliked for their smell and the mischief they did to their plantations, that they drove them into the mountains, where they run wild. The breed of cats has succeeded, and they are found to be extremely useful; and rabbits have been introduced, but we know not with what success. Common poultry are abundant, and the woods supply vast quantities of wild pigeons and parrots. The tropical bird builds its nest in the steep cliffs, and as its long feathers are highly valued, it is taken on the nest by lowering down a man seated across a stick, by a rope, to the depth of thirty or forty fathoms; in which situation, by means of a long pole, he swings himself from side to side, examining all the holes as he descends, in order to take the bird on her nest. The shores abound with sea-fowl, and the sea with excellent fish, which they take with great expertness by hook and line, or by the net. Dolphins are caught at a distance from the shore, by baiting the hook with a real or artificial flying fish. Their fishing-tackle displays the greatest ingenuity, and can only be exceeded by their skill in using it. Their hooks are made of pearl-shells, bone, and hard wood. The coast abounds with lobsters, crabs, and various kinds of shell-fish.

Inhabitants.

The colour of the natives is that of olive, or light copper. The men are above the middle size; the chiefs are almost uniformly tall, muscular, and well limbed, measuring from five feet nine inches to six feet four inches, and continue healthy and vigorous to a good old age. The women of the upper ranks are likewise tall, with limbs finely turned. Their skins are soft and delicate; their eyes black, sparkling, and full of expression; their teeth beautifully white and even; their hair jet black, and generally ornamented with flowers; and in their gait they are firm, but easy and graceful. From a custom of compressing the face when infants, they can scarcely be called beauties; yet, according to the account of Captain Wilson, they possess feminine graces in an eminent degree; " their faces never being darkened with a scowl, or covered with a cloud of sullenness or suspicion." They are affable and engaging; mild, gentle, and unaffected; courteous to each other and to strangers. The whole of the body to the middle of the leg is clothed; but there is a singular custom which compels a woman to uncover her shoulders and breasts in the presence of a chief, or in passing a Morai or sacred place. The lower classes have always been described as extremely licentious, but Captain Cook says they have been much calumniated. " It is too true," say the writers of the Missionary Voyage, " that, for the sake of gaining our extraordinary curiosities, and to please our brutes, they have appeared immodest in the extreme. Yet they lay the charge wholly at our door, and say the Englishmen are ashamed at nothing, and that we have led them to public acts of indecency never before practised amongst themselves." It must be admitted, however, that the most abandoned conduct is freely indulged by the women of the Arreoy society, who, to the crime of unbounded licentiousness, add that of murdering their children the moment they are born. In recent accounts, however, it is stated that this horrible practice has been abolished, and that Christianity is making a rapid progress amongst these interesting islanders. As wives, the Otaheitan women are tenderly affectionate to their husbands and children, nursing and attending the latter with the utmost care. They never, on any occasion, strike a child. A melancholy instance of the fidelity and affection of one of these women is given in the Missionary Voyage. "The history of Peggy Stewart marks a tenderness of heart that never will be heard without emotion. She was daughter of a chief, and taken for his wife by Mr Stewart, one of the unhappy mutineers of the Bounty. They had lived with the old chief in the most tender state of endearment; a beautiful little girl had been the fruit of their union, and was at the breast when the Pandora arrived, seized the criminals, and secured them in irons on board the ship. Frantic with grief, the unhappy Peggy flew with her infant in a canoe to the arms of her husband. The interview was so affecting and afflicting, that the officers on board were overwhelmed with anguish; and Stewart himself, unable to bear the heart-rending scene, begged she might not be admitted again on board. She was separated from him by violence, and conveyed on shore in a state of despair and grief too big for utterance. Withheld from him, and forbidden to come any more on board, she sunk into the deepest dejection; it preyed on her health, she lost all relish for food and life, rejoiced no more, and pining under a rapid decay of two months, fell a victim to her feelings, dying literally of a broken heart."

The Otaheitans are generous even to a fault; they seem to be utterly unable to resist importunities, and always ready to share their last morsel with their neighbours. Poverty is no reproach, but affluence with covetousness brings contempt on the possessor. Should any one, indeed, refuse to share his property in cases of distress, the chances are that it will be destroyed, and his house pulled down over his head. The office of king is hereditary in one family; the chiefs resemble our ancient barons; under them are the vassals, and below them the *villeins* or labourers. The king and queen enjoy many privileges, one of which is, to be carried about everywhere on men's shoulders; and the reason of this is, that whatever soil they tread upon becomes sacred, and belongs to them; so also, if they enter a house, it is rendered sacred, and becomes their property. Their domestics and attendants are also *raa*, or sacred, and for thieving, plunder, and all manner of licentiousness, they are said to be the worst on the island.

In the Missionary Voyage an account is given of the ceremony of investing the new sovereign with the royal *maro*, when each chief of the island, amounting to nearly one hundred, brings one, two, or three human victims, to offer up on the occasion. They are brought before the sovereign in a lifeless state, having first been stoned to death, or knocked on the head with clubs. From each of these victims the priest scoops out an eye, and presents it to the king on a plantain leaf, and the bodies are then carried away and interred in the Morai. The reason assigned for this oblation is, that the head being accounted sacred, and the eye the most precious part, it is presented to the king as the head and eye of the people. During the presentation, the king holds his mouth open, as if devouring it, whereby it is imagined he receives additional wisdom and discernment. The royal *maro*, and the sacred canoes which brought the human sacrifices, are then deposited in the Morai; after which a series of feasts begin, which continue for two months. These abominable rites, if not entirely abolished, have in a great degree ceased by the influence of the missionaries.

In their language and their deities may be traced their Hindu origin; and though their religion is a tissue of superstitious and brutal ceremonies, they never draw near to their Eatova with carelessness and inattention. Captain Cook testifies to the decorous conduct of an Otaheitan on such occasions: "He is all devotion; he approaches the place of worship with reverential awe, uncovers when he treads on sacred ground, and prays with a fervour that would do honour to a better profession."

The early visits of the European navigators to these islands produced no advantages whatever to the inhabitants, who were only contaminated by the vices, without participating in the blessings, of civilized life. But, in later years, the visits of the missionaries to this and the other islands were solely for the purpose of improving the inhabitants, and of spreading among them the light of knowledge and of truth. A great improvement has in consequence taken place in the manners as well as in the morals of these savages. It was in the year 1796 that the London Missionary Society sent out their first missionaries to Otaheite, and to the South Seas. Their object was to communicate the knowledge of Christianity to the natives, who gladly received them, as well as several others who were afterwards sent out in the year 1800. The missionaries were, however, involved in serious trouble in 1799, from the thievish habits and riotous dispositions of the natives; and several of them were compelled to take refuge in New South Wales, whence they afterwards returned to Otaheite. Their prospects were for a long time uncertain and precarious; and they laboured with very little success to draw the attention of the natives from their cruel rites and superstitions to the purer faith of the gospel. About the year 1814, they began, however, to make some converts. In the neighbouring island of Eimeo, about fifty persons voluntarily renounced idolatry, and embraced Christianity. These first converts were continually increased by new accessions, until the great body of the inhabitants, as well as those in seven or eight of the neighbouring islands, embraced Christianity, and renounced their former impure and idolatrous rites. They now assemble regularly for public worship, as decently attired as they can afford, in congregations of four or five hundred, and occasionally seven or eight hundred persons. Their imitation of the European dress is not, however, always the most successful. They are extremely fond of gaudy colours; and the cast-off clothes of soldiers are in particular request. Sometimes a coat is worn without a shirt or any other article of European apparel; and frequently not fitting, the effect is rather ludicrous. Along with religion, they are also instructed in all the mechanical trades of Europe; they are taught to read, write, and to cast accounts, the natives with singular industry teaching each other. Great numbers have been taught to read in the Tahitian language, which the missionaries have reduced to writing; and the Scriptures have also been translated into the native language of the island, in which language also the missionaries began to preach in 1824. A great reformation has followed the propagation of Christianity throughout the island. The bloody, ferocious, and profligate practices of the Arreoy societies have been abolished; the crime of infanticide has disappeared; and human sacrifices are also abandoned, with many other idolatrous and degrading superstitions and practices. Many of the other improvements of civilized life have been adopted. The dwellings of the chiefs have been enlarged and beautified; a distinct house has been assigned to each family, in place of their being, as formerly, all crowded into one house. Land has been cultivated, and the sugar-cane raised in some districts; and the cotton cultivation has also been commenced. This island is now frequently visited by European ships, and civilization is advancing.

It was in the year 1815 that idolatry was formally abolished in this island, under the influence of Pomare, the king, who, though his character was defective in many points, being addicted to intemperance and other vices, was nevertheless steady in his friendship to the missionaries, and protected them in their efforts to introduce civilization into the country. He was anxious also to be instructed in reading and writing; and his example has contributed to diffuse a desire for knowledge among others. Schools have been established by the wives of the missionaries, where instruction is given in sewing, in reading, and writing. In these accomplishments many of the females have made considerable proficiency; and, since 1815, reading and writing has become general among the natives. A great change has also been made in the costume; the English dress has, as far as possible, been invariably adopted, by the women especially, who appear with frills round their necks, with caps on their heads, and stockings and shoes on their feet; and their other garments are also of European materials. The men, however, showed great awkwardness in first adopting the European costume; sometimes wearing stockings on their arms, or thrusting their arms through the legs of a pair of pantaloons, and wearing them on their shoulders, or wearing a coat without a shirt, as observed by the Russian navigators, or wearing a shirt on the outside of the dress. The progress of improvement, however, is begun, and will advance; and in time society in these islands will assume the aspect of civilized life. Pomare, the king of Otaheite, and the first convert to Christianity, which he professed in 1812, was born about the year 1774. He died in the year 1821, and was immediately succeeded by his son Pomare III., who was crowned with no small pomp in 1824, being then only four years of age. Shortly after his coronation he was placed at the South Sea academy in the island of Eimeo, under the care of Mr and Mrs Orsmund, for the purpose of receiving, with the children of the Missionaries, an English education. He died in 1827, of a lingering disorder, then prevalent in the islands, and was succeeded by a daughter of Pomare II., who still reigns. The monarchy is despotic, nor does it afford any adequate security for life or property. Even Pomare, notwithstanding all his apparent religious zeal, occasionally plundered his subjects, and seized their property by main force. A long era of moral improvement must elapse before any proper form of civil order, or anything like free institutions, can be established in these islands.[1]

The missionaries accordingly experienced, after the gloss of novelty had worn off their religion, a considerable defection of their proselytes; and for a time their fair prospects of usefulness were overcast. At first the natives appeared zealous in their attachment to the Christian creed, and schools and congregations multiplied in all quarters. The same success attended the efforts of the missionaries in the neighbouring islands of Eimeo and Huaheine. In a short time, however, the people began to relapse into their former course of licentiousness, and other evil practices; and the letters of the missionaries themselves contain a full and candid account of these defections. Many of the converts, they observe, grew weary of the restraints which Christianity imposed on their passions; and the introduction of ardent spirits, the licentious example and the debauchery of the European sailors when vessels touched at the islands, the propagation of delusions among the people by visionaries, and finally a bloody war which broke out in Otaheite, completed the corruption and the defection of many converts. Another difficulty has arisen from the previous irregular and indolent habits of the natives. "A state of society," it is observed, "more dissolute, and opposed to steady application and industry, than that which prevailed among them prior to the renunciation of idolatry, cannot well be imagined; and although the general and continued operation of those propensities which heathenism had nurtured and matured was restrained almost universally when the islanders first professed Christianity, numbers being influenced by the excitement of feeling in favour of the new religion, which then appeared to pervade all classes, many afterwards relapsed into their former evil practices, and have remained destitute of everything connected with Christianity excepting the name. These found, as might have been expected, their former inclinations too strong to be restrained by the feeble resistance which public opinion interposed; and though they did not revive the worship of the idols or cruelties of human sacrifices, they returned, in a great degree, to their former indolence and vices."[2] The missionaries have spared no pains to counteract this tendency to vice. They have established throughout the island temperance societies, and have prevailed on the chiefs to restrain the importation of spirits. The Queen Pomare, and most of the chiefs, who show an ardent desire for the instruction of the people, have joined these societies, and have countenanced the efforts of the missionaries, who have in some degree succeeded in stemming the torrent of profligacy which was inundating these countries, and was fast sweeping away all traces of that purer morality which had been planted among the natives. "The demon of intemperance," says one of the missionaries, "which brought moral sterility and desolation, nipping and stunting the young plants of promise, has again disappeared; our fears have been dispelled."[3] But, even after all the defections that have taken place, a letter, dated April 1836, mentions that there are two thousand natives in church-fellowship; that two thirds of the people can read; that a great number have learned to write; and that the schools and chapels are well attended. In the different islands there are thirty-nine stations, thirty-seven schools, seven thousand scholars, and thirty-nine congregations consisting of twenty-two thousand attendants. A letter from one of the missionaries mentions that he had seen Queen Pomare in the midst of a group of little girls, teaching them words of one and two syllables.

---

[1] Missionary Chronicle for April 1835, p. 168, Letter of Mr Williams.

[2] See the Evangelical Magazine, and also the Missionary Chronicle for September 1832, p. 407. In the Evangelical Magazine for November 1833, the difficulties of the missionaries are very fairly stated. "The difficulties," it is observed, "attending the progress of the work in which our brethren are engaged have been frequently stated to the friends of the society. These have arisen from the natural indolence and fickleness of the natives, the effects of their former notorious licentiousness, which so many attempts have been made to revive; and the appearance of gross and visionary heresies, whereby a number of individuals, disaffected towards the requirements of the gospel, have sought, by pretended supernatural revelation, to counteract or destroy the effects which the word of God was producing among the people, in elevating the tone of moral feeling, and improving their social character and habits. In recent years, difficulties more formidable than any produced by these causes have arisen from other quarters; the increasing number of ships resorting to the islands for refreshments and traffic, and, with the increase of commerce, consequent profligacy, from the increased intercourse of seamen with the most depraved portions of native society; and the large importations of ardent spirits in English and American vessels, chiefly the latter, consisting of what is denominated New England rum, many vessels conveying this, and, with the exception of fire-arms and ammunition, no other article of barter with which to traffic among the natives. The activity and perseverance manifested in promoting the sale and use of these pernicious drugs, by hawking them about the islands, inducing the chiefs to engage in trade, and the establishment, by foreigners who have left ships touching at the islands, of a number of grog-shops on the shore, have occasioned the missionaries much perplexity and distress. By the retail of ardent spirits, these houses become the greatest pests in the country, the resort of the most abandoned in the islands, and the most indolent and depraved among the crews of the shipping, proving alike seductive and injurious to all within their influence, and exhibiting, in the conduct of foreigners, scenes of outrage and bloodshed unknown amongst the natives since their renunciation of paganism."

[3] Evangelical Magazine for August 1837, p. 395.

One most important benefit which has been conferred upon these islands, and a great step in the progress of improvement, has been the commencement of trade and manufactures. A number of natives have been taught to spin, and to weave the cotton into cloth, to make soap and salt, to prepare tobacco, to manufacture sugar; also a knowledge of rope-making, turnery, carpentry, and the art of working in iron. Some are employed as smiths, others in the preparation of lime, and in the construction of neat and comfortable dwellings, and also in boat and ship-building, in which many of them are adepts.

They have also begun to carry on commerce. A number of small vessels, built by the natives, of from twenty to thirty-five tons burden, are employed in fetching from a group of islands, situated two or three hundred miles eastward, cargoes of pearl-shell, which they dispose of to the English and American traders. The last returns of the trade to Otaheite mention 154 arrivals in 1836 at the port of Honolu, the capital, of which eighty are brigs and schooners belonging to the country, fifty-six to the United States, and seventeen to Great Britain.

The Marquesas.

5. *The Marquesas.*—This cluster of islands was discovered by Alvarode Mendana in 1595, and named by him Las Marquesas de Mendoça, in honour of the viceroy of Peru. Four only are described by Quiros the pilot, under the names of La Dominica, Santa Christina, San Pedro, and La Madalena. The Spaniards anchored in a port of Santa Christina, to which they gave the name of Madre de Dios, well protected from the trade-wind, and which has two excellent streams of fresh water flowing into it. The people are described as being an elegant race; the women in particular as remarkably beautiful, their complexions and general appearance being said to excel those of the women of Lima. Their dress consisted of a cloth made of the leaves of a palm-tree, with which they were covered from the breast downwards; and so civilly disposed were they, that a beautiful native woman seated herself by the side of Donna Isabel, the wife of Mendana, and began to fan her. But the Spaniards, as usual, found means to quarrel with the natives, and to drive them with their fire-arms into the woods.

The produce of the islands was hogs, fowls, fish, cocoanuts, sugar-canes, plantains, and the bread-fruit, which is described for the first time by the writer of this voyage.

Description.

Subsequent discoveries have made us nearly as well acquainted with the Marquesas as with Otaheite. Captain Cook visited them in 1774, and Captain Wilson in 1797. From these we know that they consist of eight in number, besides some smaller islands to the westward, which being seen by an American master of the name of Ingraham, he called them Washington's Islands. They had previously been seen, however, by Marchand in 1789, and may fairly be grouped as part of the Marquesas. The centre of the group may be reckoned in about the latitude of 9. 30. south, and longitude 139. 30. west.

Manners.

The manners, the religious ceremonies, the Morais, and the general appearance of the natives, are so similar to those of Otaheite, that a description of them would amount to little more than a repetition of what has already been said. They have all the good qualities of the natives of that island, and most of their bad ones; but, owing probably to a more restricted communication with strangers, a greater degree of simplicity was observable in their manners, on the first arrival of the missionaries amongst them, than in the people of Otaheite. Scarcely had they anchored in Resolution Bay (Madre de Dios), when two women, though it was dark, swam off to the ship, in the hope of meeting a favourable reception, calling out in a piteous tone, when they found they could not be admitted on board, *Waheené, waheené!* "We are women, we are women." The next morning the visit was repeated, and is thus described in the Missionary Voyage:

"Our first visitors from the shore came early; they were seven beautiful young women, swimming quite naked, except a few green leaves tied round their middle; they kept playing round the ship for three hours, calling *Waheené*, until several of the native men had got on board; one of them, being the chief of the island, requested that his sister might be taken on board, which was complied with. She was of a fair complexion, inclining to a healthy yellow, with a tint of red in her cheek; was rather stout, but possessing such symmetry of features, as did all her companions, that as models for the statuary and painter their equals can seldom be found." Captain Wilson says, that an Otaheitan woman which they had on board was far eclipsed by the Marquesan woman; but she was shocked to see a woman quite naked walking the deck, and threw over her a dress of Otaheitan cloth; but as for the rest of these females, the goats, it seems, soon stripped them of their green leaves, and left them in a state of complete nudity. On shore the women clothe themselves in decent habits.

The Marquesans are so far superior to the Otaheitans, that they sacrifice hogs only to their deities, and never men. Their houses, canoes, their dress, and the cultivation of their land, are at least equal to those of Otaheite, and they have none of those infamous Arreoy societies. Captain Porter of the American frigate Essex, after brutally massacring a number of these people upon the most frivolous pretext, charges them with cannibalism, though, from his own account, there does not appear to be the slightest ground for so injurious an imputation. To all unprejudiced navigators they have appeared as an amiable people, entertaining a great respect for old age, fond of their children instead of murdering them, as in Otaheite and some other islands, and living in peace and harmony with each other, and with their families.

These islands were visited by the missionaries, several of whom have settled amongst the natives. But it does not appear that their labours, though zealously pursued, have hitherto been attended with the desired success. The state of the people, it is said in the Missionary Magazine for April 1837, "is not that of open opposition or enmity against the gospel, but of apathy and unconcern, strengthened by deeply-rooted habits of worldliness and vice;" and the journals of the missionaries entirely agree with this account. It is with difficulty that they procure, at their several stations, a congregation of above eight persons on Sundays; sometimes they amount to twenty, but generally they pay little attention to the instructions of their teacher, and scarcely preserve decorum during the worship, conversing with each other about their ordinary concerns, and pursuing all their worldly occupations after the worship is finished. The missionaries are, however, resolved to persevere in their plans, in the hope that they may, as in the other islands, succeed in time in making an impression on the barbarous natives.[1] The distillation of spirits, which the people had been taught by a native of the Sandwich Islands, proved an additional obstacle to the success of the missionaries, as their eagerness to plunge into this vice shut their ears to all spiritual instruction.

Easter Island.

6. *Easter Island.*—This small island, not thirty miles in length, is only deserving of notice from its solitary position, its great distance from any of the islands of the Pacific, its comparative proximity to the coast of South America, and its being inhabited by a race of men who differ no more from the rest of the Polynesians than they do from

---

[1] Missionary Magazine for April, May, August, 1837, p. 195, 231, 395.

one another; having the same language, the same features, the same religious notions, and Morais constructed as they generally are in other islands. On the platforms of the latter are erected shapeless and uncouth masses of stone, carved in imitation of the human bust, with rude faces four or five feet in length, set on trunks of ten or twelve feet in height. Kotzebue, the last visiter to this island, looked, however, in vain for any traces of these statues on the spots where they are described by Cook and La Pérouse.

This island is supposed to have been discovered by the bucaneer Davis, in 1687, although some have contended for the Dutch Admiral Roggewein being the discoverer, and he it was who gave it the name of Paaschen or Easter Island, having first seen it on the day of that feast. Its latitude is 27. 5. south, and longitude 109. 46. west.

It is not remarkably fertile; but few trees are found on it, and no running stream. The natives are very industrious in raising food for their support, which consists chiefly of bananas, taro-roots, sugar-canes, sweet potatoes, and yams. By some navigators they are described as a very savage people, and by others as a mild and amiable race. The fact is, that their conduct has always corresponded with the treatment they received from strange visiters. Thus their decided hostility to Kotzebue, when he attempted to land on the island, was explained on his arrival at the Sandwich Islands. An American, commanding a schooner called the Nancy, from New London, had observed a vast multitude of seals on the shores of the small uninhabited island of Massafuero, to the westward of Juan Fernandez; and thinking it might turn out an excellent speculation, if a small establishment were formed on the island, to carry on the fishing, he set about the means of carrying this project into effect. His own crew was but just sufficient to navigate the vessel, and, there being no anchorage off the island, no part of it could be spared to catch seals. The brutal wretch therefore proceeded to Easter Island, and landing at Cook's Bay, seized and carried off twelve men and ten women to people his new colony. For the first three days they were confined in irons, and were not released till fairly out of sight of land, when the first use they made of their liberty was to jump overboard, choosing rather to perish in the waves than to be carried away they knew not whither, or for what purpose. The women, who were with difficulty restrained from following them, were carried to Massafuero, but what ultimately became of these poor creatures M. Kotzebue does not relate. No wonder, then, that such base and inhuman practices should have driven the natives to acts of hostility against all foreign intruders.

Since this general view of the Polynesian Islands was prepared, every voyager across the Pacific has made the discovery of additional groups of coral islands or reefs, or single islets just emerging above the surface of the ocean. The progressive increase of these wonderful fabrics would seem to require *time* only to choak up the whole Pacific. The reflections made by Kotzebue, on viewing these new creations, are as just as they are natural. "The spot on which I stood filled me with astonishment, and I adored in silent admiration the omnipotence of God, who had given, even to those minute animals, the power to construct such a work. My thoughts were confounded, when I considered the immense series of years that must elapse before such an island can rise from the fathomless abyss of the ocean, and become visible on the surface. At a future period they will assume another shape; all the islands will join and form a circular slip of earth, with a pond or lake in the circle; and this form will again change, as these animals continue building, till they reach the surface, and then the water will one day vanish, and only one great island be visible. It is a strange feeling to walk about on a living island, when all below is actively at work. And to what corner of the earth can we penetrate where human beings are not already to be found? In the remotest regions of the earth, amidst mountains of ice, under the burning sun of the equator, nay, even in the middle of the ocean, on islands which have been formed by animals, they are met with."

But not to islands alone are the operations of these zoophytes confined. Flinders found the coral reefs extending for seven hundred miles along the eastern coast of Australia, and Torres Strait is nearly choked up with them, and must in time become unnavigable. As Captain Fitzroy crossed the Pacific in the Beagle, it is to be hoped that his attention has been drawn to this curious and interesting subject; and that in his forthcoming work, or that of Mr Darwen, who accompanied him, the public will receive additional information respecting these little animals and their operations. (M.)

POLYPHEMUS, a celebrated Cyclops, and king of all the Cyclops in Sicily, was the son of Neptune and Thoosa, the daughter of Phorcys. He is said to have been a monster of great strength, very tall, and with only one eye in the middle of the forehead. He ate human flesh, and kept his flocks on the coasts of Sicily, when Ulysses, on his return from the Trojan war, was driven thither. Ulysses, together with twelve of his companions, visited the coast, and along with them was seized by the Cyclops, who confined them in his cave, and daily devoured two of them. Ulysses would have shared the fate of the rest, had he not intoxicated the Cyclops, and put out his eye with a firebrand when he was asleep. Polyphemus was awakened by the sudden pain, and stopped the entrance of his cave; but Ulysses escaped by creeping between the legs of the rams of the Cyclops, as they were led out to feed on the mountains. Polyphemus became enamoured of Galatea; but his addresses were disregarded, and the nymph shunned his presence. The Cyclops became still more earnest; and when he saw Galatea surrender herself to the pleasures of Acis, he crushed his rival with a piece of a broken rock.

POLYPLECTRON, from the Greek πολυ, *much*, and πλῆκτρον, a musical instrument invented by Dietz about ten years ago, and played upon in the manner of a piano-forte. Its sounds are produced by the friction of numerous narrow slips of leather made to revolve upon a cylinder and over pullies, and brought into contact with the strings by pressing down the finger-keys. The powers of this instrument were highly commended by Prony, Savart, Cherubini, Paer, and others, after they had made trial of it on the 11th of July 1828. According to the touch, firm and *legato*, or light and *staccato*, the quality of the tone varied. The lower sounds and medium ones closely resembled those of the double bass, violoncello, and viola. Dietz had not succeeded in imitating the sounds of a violin. The *orchestrino* of Poulleau, and some other instruments on the same principle, preceded Dietz's polyplectron.

POLYPUS, a species of fresh-water insects. The name of *hydra* was given to them by Linnæus, on account of the property they have of reproducing themselves when cut in pieces, every part soon becoming a perfect animal. Dr Hill called them *biota*, on account of the strong principle of life with which every part of them is endowed. These animals were first discovered by Leeuwenhoeck, who gave some account of them in the Philosophical Transactions for 1703; but their wonderful properties were not thoroughly known till the year 1740, when Mr Trembley began to investigate them. Previously to his discoveries, indeed, Leibnitz and Boerhaave, by reasonings *a priori*, had concluded that animals might be found which would propagate by slips like plants. Their conjectures have been verified.

Marine Polypus is different in form from the fresh-water polypus already described, but is nourished, increases, and may be propagated after the same manner; Mr Ellis having often found, in his inquiries, that small pieces cut off from the living parent, in order to view the several parts more accurately, soon gave indications that they contained not only the principles of life, but likewise the faculty of increasing and multiplying into a numerous issue. It has been proved by Peyssonel, Ellis, Jussieu, Reaumur, Donati, and others, that many of those substances which had formerly been considered by naturalists as marine vegetables or sea-plants, are in reality animal productions; and that they are formed by polypuses of different shapes and sizes, for their habitation, defence, and propagation. To this class may be referred the corals, corallines, keratophyta, eschara, sponges, and alcyonium; nor is it improbable that the more compact bodies, known by the common appellations of star-stones, brain-stones, petrified fungi, and the like, brought from various parts of the East and West Indies, are of the same origin. To this purpose Mr Ellis observes, that, in all the warmer latitudes, the ocean, near the shore, and wherever it is possible to observe, abounds so much with animal life, that no inanimate body can long remain in it unoccupied by some species. In these regions ships' bottoms are soon covered with the habitations of thousands of animals; rocks, stones, and everything lifeless are instantly covered with them; even the branches of living vegetables which hang into the water are immediately loaded with the spawn of different animals, shell-fish of various kinds; and shell-fish themselves, when they become impotent and old, are the basis of new colonies of animals, from whose attacks they can no longer defend themselves.

POLYSEMASIA, from the Greek πολυ and σημασια, a term applied to such intervals and chords in harmony, as produce upon the ear the same effect, although they may differ from each other in notation; for example, ♭B G ♯A G; B D F ♭A, B D ♯E ♯G, &c. Also such chords as, although expressed by the same notes, are yet referrible to different harmonic foundations.

POLYSPERMOUS, from πολυ, *much*, and σπεϱμα, *seed*, in *Botany*, is applied to such plants as have more than four seeds succeeding each flower, without any certain order or number.

POLYSYLLABLE, in *Grammar*, a word consisting of more than three syllables. When a word consists of one, two, or three syllables, it is called a *monosyllable*, a *dissyllable*, or a *trisyllable*.

POLYTHEISM.

Definition.

Polytheism is the doctrine of a plurality of gods, or invisible powers superior to man.

"That there exist beings, one or many, powerful above the human race, is a proposition," says Lord Kames,[1] "universally admitted as true in all ages and among all nations. I boldly call it *universal*, notwithstanding of what is reported of some gross savages; for reports that contradict what is acknowledged to be general among men, require more able vouchers than a few illiterate voyagers. Among many savage tribes there are no words but for objects of external sense; is it surprising that such people are incapable of expressing their religious perceptions, or any perception of internal sense? The conviction that men have of superior powers, in every country where there are words to express it, is so well vouched, that in fair reasoning it ought to be taken for granted among the few tribes where language is deficient."

Source of religious principles traced.

These are judicious observations, of which every man will admit the force who has not some favourite system to build upon the unstable foundation which his lordship overturns. Taking it for granted, then, that our conviction of superior powers has long been universal, the important question is, from what cause it proceeds. The same ingenious author shows, with great strength of reasoning, that the operations of nature and the government of this world, which to us loudly proclaim the existence of a Deity, are not sufficient to account for the universal belief of superior beings amongst savage tribes. He is therefore of opinion that this universality of conviction can spring only from the image of Deity stamped upon the mind of every human being, the ignorant equally with the learned. "Nothing less," he says, "is sufficient; and the original impression which we have of Deity must proceed," he thinks, "from an internal sense, which may be termed the *sense of Deity*."

We have elsewhere expressed our opinion of that philosophy which accounts for every phenomenon in human nature by attributing to it a particular instinct; but to this instinct or sense of Deity, considered as complete evidence, many objections, more than usually powerful, force themselves upon us. All nations, except the Jews, were once polytheists and idolaters. If, therefore, his lordship's hypothesis be admitted, either the doctrine of polytheism must be true theology, or this instinct or sense is of such a nature as, at different periods of the world, to have misled all mankind. All savage tribes are at present polytheists and idolaters; but amongst savages every instinct appears in greater purity and vigour than amongst people polished by arts and sciences; and instinct never mistakes its object. The instinct or primary impression of nature, which gives rise to self-love, affection between the sexes, love of progeny, &c. has in all nations, and in every period of time, a precise and determinate object, which it inflexibly pursues. How then comes it to pass that this particular instinct, which, if real, is surely of as much importance as any other, should have uniformly led those who had no other guide to pursue improper objects, to fall into the grossest errors and the most pernicious practices? To no purpose are we told, that the sense of Deity, like the moral sense, makes no capital figure amongst savages. There is reason to believe that the feeling or perception, which is called the *moral sense*, is not wholly instinctive; but whether it be or not, a single instance cannot be produced in which it multiplies its objects, or makes even a savage express gratitude to a thousand persons for benefits which his prince alone had power to confer.

For these and other reasons which might easily be assigned, we cannot help thinking, that the first religious principles must have been derived from a source different as well from internal sense as from the deductions of reason; from a source which the majority of mankind had early forgotten, and which, when it was banished from their minds, left nothing behind it to prevent the very first principle of religion from being perverted by various accidents or causes, or, in some extraordinary concurrence of circumstances, from being perhaps entirely obliterated. This source of religion every consistent theist must believe to be revelation. Reason, it is acknowledged, could not have introduced savages to the knowledge of God; and we have

---

Theism.

just seen that a sense of Deity is an hypothesis clogged with insuperable difficulties. Yet it is undeniable that all mankind have believed in superior invisible powers; and if reason and instinct be set aside, there remains no other origin of this universal belief than primeval revelation, corrupted, indeed, as it passed by oral tradition from father to son, in the course of many generations. It is no slight support to this doctrine, that if there really be a Deity,[1] it is highly presumable that he would reveal himself to the first men; creatures whom he had formed with faculties to adore and to worship him. To other animals the knowledge of a Deity is of no importance; to man it is of the first importance. Were we totally ignorant of a Deity, this world would appear to us a mere chaos. Under the government of a wise and benevolent Deity, chance is excluded; and every event appears to be the result of established laws. Good men submit to whatever happens without repining, knowing that every event is ordered by Divine Providence; they submit with entire resignation, and such resignation is a sovereign balsam for every misfortune or evil in life.

Admitting, then, that the knowledge of Deity was originally derived from revelation, and that the first men professed pure theism, it shall be our business in the present article to trace the rise and progress of polytheism and idolatry; and to ascertain, if we can, the real opinions of the pagan world concerning that multitude of gods with which they filled heaven, earth, and hell. In this inquiry, though we shall have occasion to appeal to the writings of Moses, we shall attribute to them no other authority than what is due to records of the earliest ages, more ancient and authentic than any others that are now extant.

Whether we believe, with the author of the book of Genesis, that all men have descended from the same progenitors, or adopt the hypothesis of modern theorists, that there have been successive creations of men, and that the European derives his origin from one pair, the Asiatic from another, the woolly-headed African from a third, and the copper-coloured American from a fourth, polytheism and idolatry will be seen to have arisen from the same causes, and to have advanced nearly in the same order from one degree of impiety to another. On either supposition, it must be taken for granted, that the original progenitors were instructed by their Creator in the truths of genuine theism; and there is no room to doubt that those truths, simple and sublime as they are, would be conveyed pure from father to son as long as the race lived in one family, and were not spread over a large extent of country. If any credit be due to the records of antiquity, the primeval inhabitants of this globe lived to so great an age, that they must have increased to a very large number long before the death of the common parent; who would of course be the bond of union to the whole society, and whose dictates, especially in what related to the origin of his being and the existence of his Creator, would be listened to with the utmost respect by every individual of his numerous progeny.

ircumstances hich led poly- heism.

Many causes, however, would conspire to dissolve this family, after the death of its ancestor, into separate and independent tribes, of which some would be driven by violence, or would voluntarily wander, to a distance from the rest. From this dispersion great changes would take place in the opinions of some of the tribes respecting the object of their religious worship. A single family, or a small tribe, banished into a desert wilderness, such as the whole earth must then have been, would find employment for all their time in providing the means of subsistence, and in defending themselves from beasts of prey. In such circumstances they would have little leisure for meditation, and being constantly conversant with objects of sense, they would gradually lose the power of meditating upon the spiritual nature of that Being by whom their ancestors had taught them that all things were created. The first wanderers would no doubt retain in tolerable purity their original notions of Deity, and they would certainly endeavour to impress those notions upon their children. But, in circumstances infinitely more favourable to speculation than theirs could have been, the human mind dwells not long upon notions that are purely intellectual. We are so accustomed to sensible objects, and to the ideas of space, extension, and figure, which they are perpetually impressing upon the imagination, that we find it extremely difficult to conceive any being without assigning to him a form and a place. Hence a learned writer[2] has supposed that the earliest generations of men, even those to whom he contends that frequent revelations were vouchsafed, may have been no better than anthropomorphites in their conceptions of the Divine Being.

Origin of Polytheism.

First steps in the progress.

Be this as it may, it is not conceivable but that the members of those first colonies would quickly lose many of the arts and much of the science which perhaps prevailed in the parent state; and that, fatigued with the contemplation of intellectual objects, they would relieve their overstrained faculties, by attributing to the Deity a place of abode, if not a human form. To men totally illiterate, the place fittest for the habitation of the Deity would undoubtedly appear to be the sun, the most beautiful and glorious object of which they could form any idea; an object, too, from which they could not but be sensible that they received the benefits of light and heat, and which experience must soon have taught them to be in a great measure the source of vegetation. The great spirit, therefore, inhabiting the sun, which they would consider as the power of light and heat, was in all probability the first object of idolatrous adoration.

The spirit of light the first god of paganism.

From looking upon the sun as the habitation of their god, they would soon proceed to consider it as his body. Of pure mind entirely separated from matter, men in their circumstances could not long retain the faintest notion; but conscious each of power in himself, and experiencing the effects of power in the sun, they would naturally conceive that luminary to be animated as their bodies were animated. They would feel his influence when above the horizon; they would see him moving from east to west; they would consider him when set as gone to take his repose; and those exertions and intermissions of power being analogous to what they experienced in themselves, they would look upon the sun as a real animal. Thus would the Divinity appear to their untutored minds to be a compound being like man, partly corporeal and partly spiritual; and as soon as they imbibed such notions, though perhaps not before, they may be pronounced to have been absolute idolaters.

The spirit or power of darkness the second.

When men had once got into this train, their gods would multiply upon them with wonderful rapidity. Darkness and cold they could not but perceive to be contrary to light and heat; and not having philosophy enough to distinguish between mere privations and positive effects, they would consider darkness and cold as entities equally real with light and heat, and attribute these different and contrary effects to different and contrary powers. Hence the spirit or power of darkness was in all probability the second god in the pagan calendar; and as they considered the power of light as a benevolent principle, the source of all that is good, they must have looked upon the contrary power of darkness as a malevolent spirit, the source of all that is evil.

Polytheism of the Persian Magi.

This we know from authentic history to have been the belief of the Persian Magi, a very ancient sect, who called their good god Yazdun, and also Ormuzd, and the evil god Ahriman. Considering light as the symbol, or perhaps as the body, of Ormuzd, they always worshipped him before

Magianism.

the fire, the source of light, and especially before the sun, the source of the most perfect light; and for the same reason fires were kept continually burning on his altars. That they sometimes addressed prayers to the Evil Principle, we are informed by Plutarch in his Life of Themistocles; but with what particular rites he was worshipped, or where he was supposed to reside, it is not so evident. Certain it is, however, that the worshippers held him in detestation; and when they had occasion to write his name, they always inverted it, to denote the malignity of his nature. The principles of the Magi, though widely distant from pure theism, were much less absurd than those of other idolaters. It does not appear that they ever worshipped their gods through the medium of graven images, or had any other emblems of them than light and darkness. Indeed we are told by Diogenes Laertius and Clemens Alexandrinus, that they condemned all statues and images, allowing fire and water to be the only proper emblems or representatives of their gods: And we learn from Cicero,[1] that at their instigation Xerxes was said to have burned all the temples of Greece, because the builders of those edifices impiously presumed to enclose within walls the gods, to whom all things ought to be open and free, and whose proper temple is the whole world. To these authorities we may add that of all the historians, who agree, that when the creed of the Magi was the religion of the court, the Persian monarchs made war upon images, and upon every emblem of idolatry different from their own.

Tsabaian polytheism.

The Magi, however, were but one sect, and not the largest, of ancient idolaters. The worship of the sun, as the source of light and heat, soon introduced into the calendar of divinities the other heavenly bodies, the moon, the planets, and the fixed stars. Men could not but experience great benefit from those luminaries in the absence of their chief god; and when they had proceeded so far as to admit two divine principles, a good and an evil, it was natural for minds clouded with such prejudices to consider the moon and the stars as benevolent intelligences, sent to oppose the power of darkness whilst their first and greatest divinity was absent or asleep. It was thus, as they imagined, that he maintained a constant superiority over the Evil Principle. Though to astronomers the moon is known to be an opaque body of very small dimensions when compared with a planet or a fixed star, yet to the vulgar eye she appears much more magnificent than either. By those early idolaters she was considered as the divinity second in rank and in power; and whilst the sun was worshipped as the king, she was adored as the queen, of heaven.

The earth, considered as the common mother of all things; the ocean, the waters of which are never at rest; the air, the region of storms and tempests; and indeed all the elements, were gradually added to the number of divinities. Not that mankind in this early age had so far degenerated from the principles of their ancestors as to worship brute matter. If such worship was ever practised, which to us is hardly conceivable, it must have been at a later period, when it was confined to the very lowest of the vulgar, in nations otherwise highly civilized. The polytheists of whom we now treat conceived everything in motion to be animated, and animated by an intelligence powerful in proportion to the magnitude of the body moved.

This sect of idolaters, which remains in some parts of the East to this day, was known by the name of Tsabaians, which they pretended to have derived from a son of Seth; and amongst the books in which their sacred doctrines are contained, they have one which they call the Book of Seth. We need hardly observe, that these are senseless and extravagant fables. The epithet *Tsabaian* is undoubtedly derived from the Hebrew word *Tsaba*, which signifies an host or army; and this class of polytheists was so called, because they worshipped the host of heaven, or the *Tsaba hesemim*, against which Moses so pathetically cautions the people of Israel.[2]

Tsabaism.

Tsabaism arose in Chaldæa.

This species of idolatry is thought to have first prevailed in Chaldæa, and to have been that from which Abraham separated himself, when, at the command of the true God, he "departed from his country, and from his kindred, and from his father's house." But as it nowhere appears that the Chaldæans had fallen into the savage state before they became polytheists and idolaters, and as it is certain that they were not savages at the period of the call of Abraham, their early Tsabaism may be thought inconsistent with the account which we have given of the origin of that species of idolatry. If a great and civilized nation was led to worship the host of heaven, why, it may be asked, should that worship be supposed to have arisen amongst savages? Theories, however plausible, cannot be admitted in opposition to ascertained facts.

True; but we beg leave to reply, that our account of the origin of polytheism is opposed by no fact, because we have not supposed that the worship of the host of heaven arose amongst savages only. That savages, between whom it is impossible to imagine any intercourse to take place, have universally worshipped, as their first and supreme divinities, the sun, moon, and stars, is a fact evinced by every historian and by every traveller; and we have shown how their rude and uncultivated state naturally leads them to that species of idolatry. But there may have been circumstances peculiar to the Chaldæans, which led them likewise to the worship of the heavenly host, even in a state of high civilization. We judge of the philosophy of the ancients by that of ourselves, and imagine that the same refined system of metaphysics was cultivated by them as by the followers of Descartes and Locke. But this is a great mistake; for so gross were the notions of early antiquity, that it may be doubted whether there was a single man, uninspired, who had any notion of mind as a being distinct and entirely separated from matter. From several passages in the books of Moses, we learn, that when in the first ages of the world the Supreme Being condescended to manifest his presence to men, he generally exhibited some sensible emblem of his power and glory, and declared his will from the midst of a preternatural fire. It was thus that he appeared to the Jewish lawgiver himself, when he spoke to him from the midst of a bush; it was by a pillar of cloud and fire that he led the Israelites from Egypt to the Land of Promise; and it was in the midst of smoke, and fire, and thunderings, that the law was delivered from Mount Sinai. That such manifestations of the divine presence would occasionally be made to the descendants of Noah who settled in Chaldæa soon after the Deluge, must appear extremely probable to every one who admits the authority of the Hebrew Scriptures; and he who questions that authority has no right to make the objection to which we now reply, because it is only from the book of Genesis that we know the Chaldæans to have been a civilized people when they fell into idolatry. All histories agree in representing the inhabitants of Chaldæa as at a very early period corrupted by luxury, and sunk in vice. When this happened, we must suppose that the moral governor of the universe would withdraw from them those occasional manifestations of himself, and leave them to their own inventions. In such circumstances, it was not unnatural for a people addicted to the study of astronomy, who had been taught to believe that the Deity frequently appeared to their ancestors in a flame of fire, to consider the sun as the place of

Tsabaism.

his permanent residence, if not as his body. But when either opinion was firmly established, polytheism would be its inevitable consequence, and the progress of Tsabaism would, in the most polished nation, be such as we have traced it amongst savage tribes.

It passed into Egypt, &c.

From Chaldæa the idolatrous worship of the host of heaven spread itself over all the East, passed into Egypt, and thence found its way into Greece; for Plato affirms,[1] that "the first inhabitants of Greece seemed to him to have worshipped no other gods but the sun, moon, earth, stars, and heavens, as most barbarous nations," continues he, "still do." That Tsabaism, or the worship of the host of heaven, was the first species of idolatry, besides the probability of the thing, and the many allusions to it in sacred Scripture, we have the positive evidence of the most ancient pagan historians of whose writings any part has been transmitted to us. Herodotus,[2] speaking of the religion of the Persians, says that "they worship the sun, moon, and earth, fire, water, and the winds; and this adoration they have all along paid from the beginning." He testifies the same thing of the savage Africans, of whom he affirms,[3] that they all worshipped the sun and moon, and no other divinity. Diodorus Siculus, writing of the Egyptians,[4] tells us that "the first men, looking up to the world above them, and terrified and struck with admiration at the nature of the universe, supposed the sun and the moon to be the principal and eternal gods." And Sanchoniathon the Phœnician, a more ancient writer than any of these, informs us, in the fragment of his history preserved by Eusebius, that "the two first mortals were Æon and Protogonus, and their children Genos and Genea, who inhabited Phœnicia; and when they were scorched with the heat, they lifted up their hands to the sun, whom they believed to be the lord of heaven, and called him *Baalsamen*, the same whom the Greeks call Ζευς."

Statue-worship.

Hitherto those divinities were worshipped in person, or, as Dr Prideaux expresses it, in their *sacella*, or sacred tabernacles; for the votaries of each directed their devotions towards the planet which they supposed to be animated by the particular intelligence whom they meant to adore. But these orbs, by their rising and setting, being as much below the horizon as above it, and their grossly ignorant worshippers not supposing it possible that any intelligence, however divine, could exert its influence except in union with some body, statues or pillars were soon thought of as proper emblems of the absent gods. Sanchoniathon, in the fragment already quoted, informs us, that "*Hyspouranios* and his brother *Ousous*, Phœnician patriarchs, erected two pillars, the one to fire, and the other to air or wind, and worshipped those pillars, pouring out to them libations of the blood of the wild beasts hunted down in the chase." As these early monuments of idolatry were called βαιτυλια, a word evidently derived from the Hebrew *Bethel*, the probability is, that they were altars of loose stones, such as that which was built by Jacob,[5] and from him received the same name. As his was consecrated to the true God, theirs were consecrated to the host of heaven; and the form of consecration seems to have been nothing more than the anointing of the stone or pillar with oil,[6] in the name of the divinity whom it was intended to represent. When this ceremony was performed, the ignorant idolaters, who fancied that their gods could not hear them except when they were visible, supposed that the intelligences by which the sun and planets were animated took possession, in some inexplicable manner, of the consecrated pillars, and were as well pleased with the prayers and praises offered up before those pillars, as with the devotions which were addressed towards the luminaries themselves. Hence Sanchoniathon calls them *animated* or *living stones*, λιθους ἐμψυχους, from the portion of the divine spirit which was believed to reside in them; and as they were dedicated to the host of heaven, they were generally erected upon the tops of mountains, or, in countries which, like Egypt, were low and level, they were elevated to a great height by the labour of men.

Statue-Worship.

The idolatry of high places.

It has been supposed that this practice of raising the pillars on *high places* proceeded from a desire to make the objects of worship conspicuous and magnificent. But we are strongly inclined to believe, that the erectors of βαιτυλια had something further in view, and that they thought of nothing less than to bring the sacred stone or pillar as near as possible to the god whom it represented. But whatever there be in this, we know that the practice itself prevailed universally throughout the East; and that there was nothing which the Jewish legislator more strictly enjoined his people to destroy, than the altars, statues, and pillars erected for idolatrous worship upon mountains and high places. "Ye shall utterly destroy," says he, "all the high places wherein the nations which ye shall possess served their gods, upon the *high mountains*, and upon the *hills*, and under every green tree. And ye shall overthrow their *altars*, and break down their *pillars*, and burn their *groves* with fire."[7]

The mention of *groves* by the Hebrew lawgiver brings to our recollection another species of idolatry, which was perhaps the second in order, as men deviating from the principles of pure theism became more and more entangled in the labyrinths of error. The Chaldæans, Egyptians, and all the eastern nations who believed in a superintending providence, imagined that the government of this world, the care of particular nations, and even the superintendence of groves, rivers, and mountains, in each nation, was committed by the gods to a class of spirits superior to the soul of man, but inferior to those heavenly intelligences which animated the sun, the moon, and the planets. These spirits were by the Greeks called δαιμονες, *dæmons*, and by the Romans *genii*. Timæus the Locrian, who flourished before Plato, speaking of the punishment of wicked men, says,[8] all these things has Nemesis decreed to be executed in the second period, by the ministry of vindictive terrestrial dæmons, who are overseers of human affairs; to which dæmons the Supreme God, the ruler over all, has committed the government and administration of this world, which is made up of gods, men, and animals.

Origin of dæmon-worship.

Concerning the origin of these intermediate beings, scholars and philosophers have framed various hypotheses. The belief of their existence may have been derived from five different sources.

Firstly, it seems to have been impossible for the limited capacities of those men, who could not form a notion of a God divested of a body and a place, to conceive how the influence and agency of such a being could every instant extend to every point of the universe. Hence, as we have seen, they placed the heavenly regions under the government of a multitude of heavenly gods, the sun, the moon, and the stars. But as the nearest of those divinities was at an immense distance from the earth, and as the intelligence animating the earth itself had sufficient employment in regulating the general affairs of the whole globe, a notion insinuated itself into the untutored mind, that these superior governors of universal nature found it necessary, or at least expedient, to employ subordinate intelligences or dæmons, as ministers to execute their behests in the various parts of their widely extended dominions.

Dæmons.

Secondly, such an universal and uninterrupted course of action as was deemed necessary to administer the affairs of the universe, would be judged altogether inconsistent with that state of indolence which, especially in the East, was held an indispensable ingredient in perfect felicity. It was this notion, absurd as it is, which made Epicurus deny the providence, whilst he admitted the existence, of gods. And if it had such an effect upon a philosopher who in the most enlightened ages had many followers, we need not surely wonder if it made untaught idolaters imagine that the governor or governors of the universe had devolved a great part of their trouble on deputies and ministers.

Thirdly, when men came to reflect on the infinite distance between themselves and the gods, they would naturally form a wish that there might somewhere exist a class of intermediate intelligences, whom they might employ as mediators and intercessors with their far-distant divinities. But what men earnestly wish for, they very readily believe. Hence the supposed distance of their gods would, amongst untutored barbarians, prove a fruitful source of intermediate intelligences, more pure and more elevated than human souls.

Fourthly, these three opinions may be denominated popular; but that which we are now to state, wherever it may have prevailed, was the offspring of philosophy. On this earth we perceive a scale of beings rising gradually above each other in perfection, from mere brute matter through the various species of fossils, vegetables, insects, fishes, birds, and beasts, up to man. But the distance between man and God is infinite, and capable of admitting numberless orders of intelligences, all superior to the human soul, and each rising gradually above the other till they reach that point, wherever it may be, at which creation stops. Part of this immense chasm the philosophers perceived to be actually filled by the heavenly bodies; for in philosophical polytheism there was one invisible God, supreme over all these; but still there was left an immense vacuity between the human species and the moon, which was known to be the lowest of the heavenly host; and this they imagined must certainly be occupied by invisible inhabitants of different orders and dispositions, which they called good and evil dæmons.

Fifthly, there is yet another source from which the universal belief of good and evil dæmons may be derived, with perhaps greater probability than from any or all of these. If the Mosaic account of the creation of the world, the peopling of the earth, and the dispersion of mankind, be admitted as true (and a more consistent account has not as yet been given or devised), some knowledge of good and evil angels must necessarily have been transmitted from father to son by the channel of oral tradition. But this tradition would be corrupted at the same time, and in the same manner, with others of greater importance. When the true God was so far mistaken as to be considered, not as the sole governor of the universe, but only as the self-existent power of light and good, the devil would be elevated from the rank of a rebellious created spirit to that of the independent power of darkness and evil; the angels of light would be transformed into good dæmons, and those of darkness into dæmons that are evil. This account of the origin of dæmonology receives no small support from Plato, who derives one branch of it wholly from tradition. "With respect to those dæmons," says he,[1] "who inhabit the space between the earth and the moon, to understand and declare their generation is a task too arduous for my slender abilities. In this case we must credit the report of men of other times, who, according to their own account, were the descendants of the gods, and had, by some means or other, gained exact intelligence of that mystery from their ancestors. We must not question the veracity of the children of the gods, even though they should transgress the bounds of probability, and produce no evidence to support their assertions. We must, I say, notwithstanding, give them credit, because they profess to give a detail of facts with which they are intimately acquainted, and the laws of our country oblige us to believe them."

Dæmons.

Though these dæmons were generally invisible, they were not supposed to be pure disembodied spirits. Proclus, in his commentary upon Plato's *Timæus*, tells us, "that every dæmon superior to human souls consisted of an intellectual mind and an ethereal vehicle." Indeed it is very little probable, that those who gave a body and a place to the Supreme God, should have thought that the inferior orders of his ministers were spirits entirely separated from matter. Plato himself divides the class of dæmons into three orders; and whilst he holds their souls to be particles or emanations from the divine essence, he affirms that the bodies of each order of dæmons are composed of that particular element in which they for the most part reside. "Those of the first and highest order are composed of pure ether; those of the second order consist of grosser air; and dæmons of the third or lowest rank have vehicles extracted from the element of water. Dæmons of the first and second orders are invisible to mankind. The aquatic dæmons, being invested with vehicles of grosser materials, are sometimes visible and sometimes invisible. When they do appear, though faintly observable by the human eye, they strike the beholder with terror and astonishment." Dæmons of this last order were supposed to have passions and affections similar to those of men; and though all nature was full of them, they were believed to have local attachments to mountains, rivers, and groves, where their appearances were most frequent. The reason of these attachments seems to be obvious. Polytheism took its rise in countries scorched by a burning sun; and dæmons by their composition being necessarily subject in some degree to the influence of heat and cold, it was natural to suppose that they, like men, would delight in the shady grove and in the purling stream. Hence the earliest altars of paganism were generally built in the midst of groves, or on the banks of rivers; because it was believed that in such places were assembled multitudes of those intelligences, whose office it was to regulate the affairs of men, and to carry the prayers and oblations of the devout to the far-distant residence of the celestial gods. Hence too are to be derived the mountain and river gods, with the dryads and hamadryads, the satyrs, nymphs, and fauns, which held a place in the creed of ancient paganism, and make so conspicuous a figure in the Greek and Roman poets.

Deification of departed heroes.

These different orders of intelligences, which, though worshipped as gods or demigods, were yet believed to partake of human passions and appetites, led the way to the deification of departed heroes, and other eminent benefactors of the human race. By the philosophers all souls were believed to be emanations from the divinity; but "gratitude and admiration, the warmest and most active affections of our nature, concurred to enlarge the object of religious worship, and to make man regard the inventors of arts and the founders of society as having in them more than a common ray of the divinity. So that god-like benefits, bespeaking as it were a god-like mind, the deceased parent of a people was easily advanced into the rank of a dæmon. When the religious bias was in so good a train, natural affection would have its share in promoting this new mode of adoration. Piety to parents would naturally take the lead, as it was supported by gratitude and admiration, the *primum mobile* of the whole system; and, in those early ages, the natural father of the tribe often happened to be the political father of the people, and the founder of the state. Fondness for the offspring would next have its turn; and a disconsolate father, at the head of a people, would contrive to soothe his grief for the untimely death of a favourite child, and to gratify his pride under the want of succession, by paying divine honours to its memory."[1] "For a father afflicted with untimely mourning, when he had made an image of his child recently taken away, now honoured him as a god, who was then a dead man, and delivered to those that were under him ceremonies and sacrifices."[2] That this was the origin and progress of the worship of departed souls, we have the authority of the famous fragment of Sanchoniathon, already quoted, where the various motives for this species of idolatry are recounted in express words. "After many generations," says he, "came *Chrysor;* and he invented many things useful to civil life, for which, after his decease, he was worshipped as a god. Then flourished *Ouranos* and his sister *Gé*, who deified and offered sacrifices to their father *Hypsistos*, when he had been torn in pieces by wild beasts. Afterwards *Kronos* consecrated *Muth* his son, and was himself consecrated by his subjects."

---

[1] *Timæus.*

In the reign of Kronos there flourished a personage of great reputation for wisdom, who by the Egyptians was denominated *Thoth*, by the Phœnicians *Taautos*, and by the Greeks *Hermes*. According to Plutarch, he was a profound politician, and chief counsellor of Osiris, then the king, and afterwards the principal divinity, of Egypt; and we are told by Philo Byblius, the translator of Sanchoniathon, "that it was this Thoth or Hermes who first took the matters of religious worship out of the hands of unskilful men, and brought them into due method and order." His object was to make religion serviceable to the interests of the state. With this view he appointed Osiris and other departed princes to be joined with the stars and worshipped as gods; and being by Kronos made king of Egypt, he was, after his death, worshipped himself as a god by the Egyptians. To this honour, if what is recorded of him be true, he had indeed a better title than most princes; for he is said to have been the inventor of letters, arithmetic, geometry, astronomy, and hieroglyphics, and was therefore one of the greatest benefactors of the human race which any age or country has ever produced.

That the gods of Greece and Rome were derived from Egypt and Phœnicia, is so universally known, that it is needless to multiply quotations in order to prove that the progress of polytheism amongst the Greeks and Romans was the same with that which we have traced in more ancient nations. The following account, given by Hesiod, of the deification of departed heroes, is so just, and in our opinion so beautiful, that we cannot refrain from introducing it in this place.

> The gods who dwell on high Olympus' hill,
> First fram'd a golden race of men, who liv'd
> Under old Saturn's calm auspicious sway.
> Like gods they liv'd, their hearts devoid of care,
> Beyond the reach of pain and piercing woes;
> Th' infirmities of age nor felt nor fear'd.
> Their nerves with youthful vigour strung, their days
> In jocund mirth they past, remote from ills.
> Now when this godlike race was lodg'd in earth,
> By Jove's high will to demigods they rose,
> And airy dæmons, who benign on earth
> Converse, the guides and guardians of mankind.
> In darkness veil'd, they range earth's utmost bound,
> Dispensing wealth to mortals. This reward
> From bounteous Jove awaits illustrious deeds.[3]

National and tutelar gods.

The deification of departed heroes and of statesmen was that which in all probability introduced the universal belief of national and tutelar gods, as well as the practice of worshipping those gods through the medium of statues cut into a human figure. When the founder of a state, or any other public benefactor, was elevated to the rank of a god, as he was believed still to retain human passions and affections, it was extremely natural to suppose that he would regard with a favourable eye that nation for which he had done so much upon earth; that he would oppose its enemies, and protect the laws and institutions which he himself had given it. By indulging the same train of sentiment, each city, and even every family of consequence, found *Lares* and *Penates* amongst their departed ancestors, to whom they paid the warmest adoration, and under whose protection they believed their private affairs to be placed. As those national and household gods were believed to be in their deified state clothed with airy bodies, so those bodies were supposed to retain the form which their grosser bodies had upon earth. The image of a departed friend might perhaps be formed by the hand of sorrowful affection, before the statue or the shrine of a deity was thought of; but when that friend or benefactor became the object of religious adoration, it was natural for his votaries to enliven their devotion by a view of his similitude. Maximus Tyrius tells us,[4] that "there is no race of men, whether barbarian or Grecian, living on the sea-coast or on the continent, wandering in deserts or living in cities, which has not consecrated some kind of symbol or other in honour of the gods." This is certainly true; but there is no good evidence that the first symbols of the gods were statues of men and women. Whilst the sun and other heavenly bodies continued to be the sole objects of religious worship, the symbols consecrated to them were pillars of a conical or pyramidal figure; and if such pillars are ever called graven images by Moses and other ancient writers, it was probably on account of the allegorical figures and characters, or hieroglyphical writing, with which they were inscribed.

Hero-worship engrafted on the planetary.

Hitherto we have considered the souls of departed heroes as holding the rank only of dæmons or demigods; but they generally rose in the scale of divinities, until they dethroned the heavenly bodies, and became themselves the *dii majorum gentium*. This revolution was effected by the combined operation of the prince and the priest; and the first step taken towards it seems to have been the complimenting of their heroes and public benefactors with the name of that being which was most esteemed and worshipped. "Thus a king for his beneficence was called the sun, and a queen for her beauty the moon. Diodorus relates, that Sol first reigned in Egypt, called so from the luminary of that name in the heavens. This will help us to understand an odd passage in the fragment of Sanchoniathon, where it is said that Kronos had seven sons by Rhea, the youngest of whom was a god as soon as born. The meaning probably is, that this youngest son was called after some luminary in the heavens to which they paid divine honours; and these honours came in process of time to be transferred to the terrestrial namesake. The same historian had before told us, that the sons of Genos, mortals like their father, were called by the names of the elements, light, fire, and flame, of which they had discovered the use."

"As this adulation advanced into an established worship, they turned the compliment the other way, and called the planet or luminary after the hero, the better to accustom the people, even in the act of planet-worship, to this new adoration. Diodorus, in the passage already quoted, having told us, that by the first inhabitants of Egypt the sun and moon were supposed to be the principal and eternal gods, adds, that the former was called Osiris, and the

Hero-Worship.

latter Isis. This was indeed the general practice; for we learn from Macrobius, that the Ammonites called the sun Moloch; the Syrians, Adad; the Arabs, Dionysus; the Assyrians, Belus; the Phœnicians, Saturn: the Carthaginians, Hercules; and the Palmyrians, Elagabalus. Again, by the Phrygians the moon was called Cybele, or the mother of the gods; by the Athenians, Minerva; by the Cyprians, Venus; by the Cretans, Diana; by the Sicilians, Proserpine; by others, Hecate, Bellona, Vesta, Urania, Lucina, &c. Philo Byblius explains this practice. 'It is remarkable,' says he, 'that the ancient idolaters imposed on the elements, and on those parts of nature which they esteemed gods, the names of their kings; for the natural gods which they acknowledged were only the sun, moon, planets, elements, and the like; they being now in the humour of having gods of both classes, the mortal and the immortal.'

"As a further proof that hero-worship was thus superinduced upon the planetary, it is worthy of observation, that the first statues consecrated to the greater hero-gods, or those who were supposed to be supreme, were not of a human form, but conical or pyramidal, like those which, in the earliest ages of idolatry, were dedicated to the sun and planets. Thus the scholiast on the *Vespæ* of Aristophanes tells us, that the statues of Apollo and Bacchus were conic pillars or obelisks; and Pausanias, that the statue of Jupiter Meilichius represented a pyramid; that of the Argive Juno did the same, as appears from a verse of Phoronis quoted by Clemens Alexandrinus;[1] and indeed the practice was universal, as well amongst the early barbarians as amongst the Greeks. But it is well known that the ancients represented the rays of light by pillars of a conical or pyramidal form; and therefore it follows, that when they erected such pillars as representatives of their hero-gods, these latter had succeeded to the titles, rights, and honours of the natural and celestial divinities."[2]

Progress of this revolution in theology.

But though it seems to be certain that hero-worship was thus engrafted on the planetary, and that some of those heroes in process of time supplanted the planets themselves, this was such a revolution in theology as could not have been suddenly effected by the united influence of the prince and the priest. We doubt not the fact that Sol was believed to have reigned in Egypt, and was afterwards worshipped under the name Osiris; but it was surely impossible to persuade any nation, however stupid or prone to idolatry, that a man, whom they remembered discharging the duties of their sovereign and legislator, was the identical sun whom they beheld in the heavens. Osiris, if there was in Egypt a king of that name, may have been deified immediately after his death, and honoured with that worship which was paid to good dæmons; but he must have been dead for ages before any attempt was made to persuade the nation that he was the Supreme God. Even then great address would be requisite to render such an attempt successful. The prince or priest who entered upon it would probably begin with declaring, on the authority of an oracle, that the divine intelligence which animates and governs the sun had descended to earth and animated the person of the renowned legislator; and that, after their laws were framed, and the other purposes served, for which the descent was made, the same intelligence had returned to its original residence and employment amongst the celestials. The possibility of this double transmigration from heaven to earth and from earth to heaven, would without difficulty be admitted in an age when the pre-existence of souls was the universal belief. Having proceeded thus far in the apotheosis of dead men, the next step taken in order to render it in some degree probable that the early founders of states, and inventors of arts, were divine intelligences clothed with human bodies, was to attribute to one such benefactor of mankind the actions of many of the same name. Vossius, who employed much time and great erudition on the subject, has proved, that before the era of the Trojan wars, most kings who were very powerful, or highly renowned for their skill in legislation, were called Jove; and when the actions of all these were attributed to one Jove of Crete, it would be easy for the crafty priest, supported by all the power and influence of the state, to persuade an ignorant and barbarous people, that he whose wisdom and heroic exploits so far surpassed those of ordinary men must have been the Supreme God in human form.

Hero-Worship.

Vices of the pagan gods accounted for.

This short sketch of the progress of polytheism and idolatry will enable the reader to account for many circumstances recorded of the pagan gods of antiquity, which at first view seem very surprising, and which at length brought the whole system into contempt amongst the philosophers of Athens and Rome. The circumstances to which we allude are the immoral characters of those divinities, and the abominable rites with which they were worshipped. Jupiter, Apollo, Mars, and the whole rabble of them, are described by the poets as ravishers of women and notorious adulterers. Hermes or Mercury was a thief, and the god of thieves. Venus was a prostitute, and Bacchus a drunkard. The malice and revenge of Juno were implacable; and so little regard was any of them supposed to pay to the laws of honour and rectitude, that it was a common practice of the Romans, when besieging a town, to evoke the tutelar deity, and to tempt him by a reward to betray his friends and votaries.[3] In a word, they were, in the language of the poet,

> Gods partial, changeful, passionate, unjust,
> Whose attributes were rage, revenge, and lust.

This was the natural consequence of their origin. Having once animated human bodies, and being supposed still to retain human passions and appetites, they were believed, in their state of deification, to feel the same sensual desires which they had felt upon earth, and to pursue the same means for their gratification. As the men could not well attempt to surpass the gods in purity and virtue, they were easily persuaded by artful and profligate priests, that the most acceptable worship which could be rendered to any particular deity was to imitate the example of that deity, and to indulge in the practices over which he presided. Hence the worship of Bacchus was performed during the night by men and women mixing in the dark after intemperate eating and drinking. Hence, too, it was the practice in Cyprus and some other countries to sacrifice to Venus the virginity of young women some days before their marriage, in order, as was pretended, to secure their chastity ever afterwards; and, if Herodotus may be credited, every woman amongst the Babylonians was obliged once in her life to prostitute herself in the temple of the goddess *Mylitte* or Venus, that she might thenceforward be proof against all temptation.

Progress of idolatry.

The progress of polytheism, as far as we have traced it, has been regular; and the enormous error of forsaking the worship of the true God being once admitted, every subsequent step appears to be natural. It would be no difficult task to prove that it has likewise been universal. Sir William Jones, the learned president of the Asiatic Society, discovered such a striking resemblance between the gods of ancient Greece and those of the pagans of Hindustan,[4] as puts it beyond a doubt that those divinities had the same origin. The Ga-

Hero-Worship.

nesa of the Hindus he has clearly proved to be the Janus of the Greeks and Romans. As the latter was represented with two and sometimes with four faces, as emblems of prudence and circumspection, the former is painted with an elephant's head, the well known symbol amongst the Indians of sagacious discernment. The Saturn of Greece and Rome appears to have been the same personage with the Menu or Satyavrata of Hindustan, whose patronymic is Vaivaswata, or *child of the sun;* a name which sufficiently marks his origin. Amongst the Romans there were many Jupiters, one of whom appears from Ennius to have been nothing more than the firmament personified.

> Aspice hoc sublime candens, quem invocant omnes Jovem.

But this Jupiter had the same attributes with the Indian god of the visible heavens, called Indra or the king, and Divespetir, or the lord of the sky, whose consort is Sachi, and whose weapon is *vajra* or the thunderbolt. Indra is the regent of winds and showers; and though the East is peculiarly under his care, yet his Olympus is the north-pole, allegorically represented as a mountain of gold and gems. With all his power he is considered as a subordinate deity, and far inferior to the Indian triad Brahma, Vishnu, and Mahadeva or Siva, who are three forms of one and the same godhead. The president having traced the resemblance between the idolatry of Rome and India through many other gods, observes, that "we must not be surprised at finding, on a close examination, that the characters of all the pagan deities melt into each other, and at last into one or two; for it seems a well-founded opinion, that the whole crowd of gods and goddesses in ancient Rome, and likewise in Hindustan, mean only the powers of nature, and principally those of the sun, expressed in a variety of ways, and by a multitude of fanciful names."

Nor is it only in Greece, Rome, Egypt, and India, that the progress of idolatry has been from planetary to hero-worship. From every account which modern travellers have given us of the religion of savage nations, it appears that those nations adore, as their first and greatest gods, the sun, moon, and stars; and that such of them as have any other divinities have proceeded in the same road with the celebrated nations of antiquity, from the worship of the heavenly bodies to that of celestial dæmons, and from celestial dæmons to the deification of dead men. It appears, likewise, that they universally believe their hero-gods and demigods to retain the passions, appetites, and propensities of men.

candina-
an and
xon ido-
try.

That the Scandinavians and our Saxon ancestors had the same notions of the gods with the other pagans whose opinions we have stated, is evident from their calling the days of the week by the names of their divinities, and from the forms of the statues by which those divinities were represented. The idol of the Sun, from which Sunday is derived, amongst the Latins *dies Solis*, was placed in a temple, where he was adored and sacrificed to; for they believed that the sun did co-operate with this idol. He was represented like a man half naked, with his face like the sun, holding a burning wheel with both hands on his breast, signifying his course round the world; and by its fiery gleams, the light and heat with which he warms and nourishes all things.

The idol of the Moon, from which comes our Monday, or *dies Lunæ*, anciently *Moonday*, appears strangely singular, being habited in a short coat like a man. Her holding a moon expresses what she is; but the reason of her short coat and long-eared cap is lost in oblivion.

Tuisco, the most ancient and peculiar god of the Germans, represented in his garment of skin, according to their ancient manner of clothing, was, next to the Sun and Moon, the idol of highest rank in the calendar of northern paganism. To him the third day in the week was dedicated; and hence has been derived the name Tuesday, anciently *Tuisday*, called in Latin *dies Martis*, though it must be confessed that Mars does not so much resemble this divinity as he does Odin or Woden.

Hero-Worship.

Odin or *Woden* was a valiant prince amongst the Saxons. His image was prayed to for victory over their enemies; which, if they obtained, they usually sacrificed to him the prisoners taken in battle. Our Wednesday, anciently *Wodensday*, is derived from his name. The northern histories represent him as the father of Thor, by Friga his wife.

Thor was placed in a large hall, sitting on a bed canopied over, with a crown of gold on his head, surmounted by twelve stars, and holding a sceptre in his right hand. To him was attributed power over both heaven and earth; and, as he was pleased or displeased, he could send thunder, tempests, plagues, earthquakes, or fair and seasonable weather, and cause fertility. From him our Thursday derives its name, anciently *Thorsday*, and amongst the Romans *dies Jovis*, as this idol may be substituted for Jupiter.

Friga represented both sexes, holding a drawn sword in the right hand and a bow in the left; denoting that women as well as men should fight in time of need. She was generally taken for a goddess; and was reputed the giver of peace and plenty, as well as the cause of love and amity. Her day of worship was called by the Saxons *Frigedeag*, now Friday, or *dies Veneris;* but the habit and weapons of this figure have a resemblance to those of Diana rather than Venus.

Seater, or *Crodo*, stood upon the prickly back of a perch. He was thin-visaged and long-haired, with a long beard, bare-headed and bare-footed, carrying in his right hand a pail of water, wherein are fruit and flowers, and holding up a wheel in his left, his coat being tied with a long girdle. His standing on the sharp fins of this fish signified to the Saxons, that by worshipping him they should pass through all dangers unhurt; by his girdle flying both ways was shown the Saxons' freedom; and by the pail with fruit and flowers was denoted that he would nourish the earth. From him, or from the Roman deity Saturn, comes Saturday.

Such were the principal gods of the northern nations. But these people had at the same time inferior deities, who were supposed to have been translated into heaven for their heroic deeds, and whose greatest happiness consisted in drinking ale out of the skulls of their enemies in the Hall of Odin. But the limits prescribed to the present article do not permit us to pursue this subject; nor is it necessary that we should do so. The attentive reader of the article MYTHOLOGY, of the histories given in this work of the various divinities of paganism, and of the different nations by whom those divinities were worshipped, will perceive that the progress of polytheism and idolatry has been uniform over the whole earth.

Animal-worship of the Egyptians.

There is, however, one species of idolatry more wonderful than anything that has yet been mentioned, and of which our readers will certainly expect some account. It is the worship of brutes, reptiles, and vegetables, amongst the Egyptians. To the Greeks and Romans, as well as to us, that superstition appeared so monstrous, that to enumerate every hypothesis, ancient and modern, by which philosophers have endeavoured to account for it, would swell this article beyond all proportion. Animal-worship prevailed at so early a period in Egypt, that the philosophers of antiquity whose writings have descended to us, had little or no advantage over the moderns in pursuing their researches into its origin; and, amongst the modern hypotheses, those of Mosheim and Warburton appear to be as plausible as any that we have seen.[1] The former of these learned writers attributes it wholly to the policy of the prince and the craft of the priest. The latter contends, with much earnestness and ingenuity, that it resulted from the use of hieroglyphical writing. We are strongly inclined to believe that both these causes contributed to the production of so portentous an effect; and that the use of hieroglyphics as sacred symbols, after they were laid aside in civil life, completed that wonderful superstition which the craft of the priest and the policy of the prince had undoubtedly begun.

---

[1] There is, however, another hypothesis which is worthy of some attention, if it were only for the learning and ingenuity of its author. The celebrated Cudworth infers, from the writings of Philo and other Platonists of the Alexandrian school, that the an-

We learn from Herodotus,[1] that in his time the number of useful animals in Egypt was so small as to be hardly sufficient for tillage and the other purposes of civil life; whilst serpents and other noxious animals, such as the crocodile, wolf, bear, and hippopotamus, abounded in that country. From this fact Mosheim very naturally concludes,[2] that the founders of society and government in Egypt would by every art endeavour to increase the number of useful animals as the number of inhabitants increased; and that with this view they would make it criminal to kill or even to hurt sheep, cows, oxen, or goats, whilst they would wage perpetual war against the noxious animals and beasts of prey. Such animals as were assisting to them in carrying on this warfare would be justly considered as in a high degree useful to society. Hence the most grievous punishments were decreed against killing, or so much as wounding, the ichneumon and ibis; because the former was looked upon as the instinctive enemy of the crocodile, and the latter of every species of serpents. The learned writer, however, observes, that in Egypt, as in other countries, people would be tempted to sacrifice the good of the public to the gratification of their own appetites, and sometimes even to the indulgence of a momentary caprice. He thinks it was found necessary to strengthen the authority of the laws enacted for the preservation of useful animals by the sanctions of religion; and he says, that with this view the priests declared that certain animals were under the immediate protection of certain gods, that some of those animals had a divine virtue residing in them, and that they could not be killed without the most sacrilegious wickedness, and incurring the highest indignation of the gods. When once the idolatrous Egyptians were persuaded that certain animals were sacred to the immortal gods, and had a divine virtue residing in them, they could not avoid viewing those animals with some degree of veneration; and the priests, taking advantage of the superstition of the people, appointed for each species of sacred animals appropriate rites and ceremonies, which were quickly followed with building shrines and temples, and approaching them with oblations and sacrifices, and other rites of divine adoration.

To corroborate this hypothesis, he observes that, besides the animals sacred over all Egypt, each province and each city had its particular animal to which the inhabitants paid their devotions. This arose from the universal practice amongst idolaters of consecrating to themselves Lares and Penates; and as the animals which were worshipped over the whole kingdom were considered as sacred to the *Dii majorum gentium*, so the animals the worship of which was confined to particular cities or provinces, were sacred to the Lares of those cities and provinces. Hence there was in Upper Egypt a city called Lycopolis, because its inhabitants worshipped the wolf; whilst the inhabitants of Thebes, or Heliopolis, paid their devotions to the eagle, which was probably looked upon as sacred to the Sun. Our author, however, holds it as a fact which will admit of no dispute, that there was not one noxious animal or beast of prey worshipped by the Egyptians till after the conquest of their country by the Persians. That the earliest gods of Egypt were all benevolent beings, he appeals to the testimony of Diodorus Siculus; but he quotes Herodotus and Plutarch as agreeing that the latter Egyptians worshipped an evil principle under the name of Typhon. This Typhon was the inveterate enemy of Osiris, just as Ahriman was of Ormuzd; and therefore he thinks it in the highest degree probable that the Egyptians derived their belief of two self-existent principles, a good and an evil, from their Persian conquerors, amongst whom that opinion had prevailed from the earliest ages.

From whatever source their belief was derived, Typhon was certainly worshipped in Egypt, not with a view of obtaining from him any good, for there was nothing good in his nature, but in hopes of keeping him quiet, and averting much evil. As certain animals had long been sacred to all the benevolent deities, it was natural for a people so besotted with superstition as the Egyptians to consecrate emblems of the same kind to their god Typhon. Hence arose the worship of serpents, crocodiles, bears, and other noxious animals and beasts of prey. It may, indeed, seem at first sight very inconsistent to deify such animals, after they had been in the practice for ages of worshipping others for being their destroyers; but it is to be remembered, that long before the deification of crocodiles, &c. the real origin

---

cient Egyptians held the Platonic doctrine of ideas existing from eternity, and constituting, in one of the persons of the godhead, the intelligible and archetypal world. Philo, he observes, did not himself consider those ideas as so many distinct substances and animals, much less as gods; but he mentions others who deified the whole of this intelligible system, as well as its several parts. Hence, when they paid their devotions to the *sensible sun*, they pretended only to worship the divine *idea* or *archetype* of that luminary; and therefore our learned author conceives that the ancient Egyptians, in falling down to bulls, and cows, and crocodiles, meant at first to worship only the divine and eternal *ideas* of those animals. He allows, indeed, that as few could entertain any thoughts at all of those eternal ideas, there were scarcely any who could persuade themselves that the *intelligible system* had so much reality in it as the *sensible things of nature*; and hence he thinks the devotion which was originally paid to the divine ideas had afterwards no higher object than the animals and vegetables of which those ideas were the eternal patterns.

This hypothesis, however, is more ingenious than satisfactory. There is no evidence that the mysterious doctrine of Plato concerning ideas had anywhere been thought of for ages after animal-worship was established in Egypt. Of the state of Egyptian theology at that early period, Philo, and the other philosophers of the Alexandrian school, had no better means of forming a judgment than we have; and they laboured under many Greek prejudices, which must have prevented them from judging with impartiality.

It must be confessed, however, that a pretty close approximation is here made to what seems to us to be the true explanation of the origin of animal-worship. The earliest form of idolatry was Tsabaism, or the worship of the host of heaven. Of this there can be no doubt whatever. But the observation of the sun, moon, and stars preceded the adoration of the heavenly host. Astronomy was the most early cultivated of all the sciences, and traces of the ancient classification still remain to attest the circumstances of its origin. The celestial bodies being first observed in pastoral countries, their groups were, from fancied resemblances to the figures of certain known animals, marked out and distinguished by the names of those animals; and, when they became objects of idolatrous worship, it was under the denominations which had thus been applied to them. In process of time, however, when Tsabaism, from a sublime idolatry, descended to a vulgar and degrading superstition, the sign was mistaken for the thing signified; the emblem was confounded with its archetype; and the animals themselves became the objects of that worship originally intended for the celestial signs or heavenly host, represented and classed in the manner already described. Such appears to us to have been the true origin of animal-worship, at least in Egypt, where almost every sign, emblem, or symbol, has either an astronomical or mythological import; and there can be no doubt that the superstition which excited the ridicule of the Roman satirist was a gross corruption of the earliest form of idolatry known in the world.

[1] Lib. ii. cap. 65.

[2] Cudworth's Intellectual System, cap. iv. No. 158.

of animal-worship was totally forgotten by the people, if they were ever acquainted with it. The crafty priest who wishes to introduce a gainful superstition, must at first employ some plausible reason to delude the multitude; but after the superstition has been long and firmly established, it is obviously his business to keep its origin out of sight.

Such is Mosheim's account of the origin and progress of that species of idolatry which was peculiar to Egypt; and with respect to the rise of animal-worship, it appears perfectly satisfactory. But the Egyptians worshipped several species of vegetables; and it surely could be no part of the policy of wise legislators to preserve them from destruction, as vegetables are useful only as they contribute to animal subsistence. We are, therefore, obliged to call in the aid of Warburton's hypothesis to account for this branch of Egyptian superstition.

That learned and ingenious author having proved,[1] with great clearness and strength of argument, that hieroglyphical writing preceded the invention of alphabetical characters, and having traced that kind of writing from such rude pictures as those which were in use amongst the Mexicans, through all the different species of curiological, tropical, and symbolical hieroglyphics (see the article HIEROGLYPHICS), shows, by many quotations from ancient authors, that the Egyptian priests wrapped up their theology in the symbolical hieroglyphics, after alphabetical characters had banished from the transactions of civil life a mode of communicating information necessarily obscure. These symbols were the figures of animals and of vegetables, denoting, from some supposed or imaginary analogy, certain attributes of their divinities; and when the vulgar, forgetting this analogy, ceased to understand them as a species of writing, and were yet taught to consider them as sacred, they could not well view them in any other light than as emblems of the divinities whom they adored. But if rude sculptures upon stone could be emblematical of the divinities, it was surely not unnatural to infer, that the living animals and vegetables which those sculptures represented must be emblems of the same divinities more striking and more sacred. Hence, the learned author thinks, arose that wonderful superstition peculiar to the Egyptians, which led them to worship not only animals and vegetables, but also a thousand chimeras of their own creation, such as figures with human bodies, and the heads or feet of brutes, or with the bodies of brutes and the heads and feet of men.

These two hypotheses combined have been thought to account sufficiently for the idolatry of Egypt, monstrous as it was. We are persuaded that, with respect to the origin of animal-worship, Mosheim is in the right;[2] and it was a very easy step indeed for people in so good training to proceed upon the crutches of hieroglyphics to the worship of plants, and those chimeras which, as they never had a real existence in nature, could not have been thought of as emblems of the divinity, had they not been used in that symbolical writing which Warburton so ingeniously attempts to explain.

To this account of the origin of animal-worship we are fully aware that some objections may occur. Animal-worship, it has been said, was not peculiar to Egypt. The Hindus, it is well known, have a religious veneration for the cow and the alligator; but there is no evidence that in India the number of useful animals was ever so small as to make the interference of the prince and the priest necessary for their preservation; neither does it appear that the Hindus adopted from any other people the worship of a self-existent principle of evil.

To this, however, it may be answered, that there is every reason to believe that animal-worship was introduced into India by a colony of Egyptians at a very remote period. That between these two nations there was an early intercourse, is universally allowed. And although the learned president of the Asiatic Society has laboured to prove, that the Egyptians derived all that wisdom for which they were famed, as well as the rudiments of their religious system, from the natives of Hindustan, he does not appear to us to have laboured with success. To examine his arguments at length would swell this article beyond its due proportion; and we have noticed some of them elsewhere (see the article PHILOLOGY). At present we shall only observe, that Sesostris undoubtedly made an inroad into India, and conquered part of the country, whilst we nowhere read of the Hindus having at any time conquered the kingdom of Egypt. Now, though the victors have sometimes adopted the religion of the vanquished, the contrary has happened so much more frequently, and is in itself a process so much more natural, that this single circumstance affords a very strong presumption that the Egyptian monarch would rather impose his gods upon the Hindus than adopt theirs and carry them back with him to Egypt. Animal-worship might likewise be introduced into Hindustan by those vast colonies of Egyptians who took refuge in that country from the tyranny and oppression of the shepherd kings. That such colonies did settle on some occasion or other in India, seems undeniable, from monuments still remaining in that country, with forms which could hardly have occurred to a native of Asia, though they are very natural as the workmanship of Africans.

We may admit that the Hindus have never adopted from the Persians or Egyptians the worship of an independent principle of evil, and yet dispose of the other part of the objection with very little difficulty. It will be seen by and by, that the Brahmins believe a kind of triad of hypostases in the divine nature, of which one is viewed as the Destroyer, and known by several names, such as Siva and Iswara. When animal-worship was introduced into Hindustan, it was not unnatural to consider the alligator as emblematical of Iswara; and hence in all probability it is that the Hindus believe that a man cannot depart more happily from this world than by falling into the Ganges, and being devoured by one of those sacred animals. Upon the whole, the animal-worship of the Hindus, instead of militating against our account of this monstrous superstition as it prevailed in Egypt, seems to lend no small support to that account, as there was unquestionably an early intercourse between the two nations, and as colonies of Egyptians settled in India.

Polytheists
acknowledged one
Supreme
God, from
whom the
other divinities were
generated.

Having thus traced the rise and progress of polytheism and idolatry as they prevailed in the most celebrated nations of antiquity, we now proceed to inquire into the real opinions of those nations concerning the nature of the gods whom they adored. And here it is evident from the writings of Homer, Hesiod, and the other poets, who were the principal theologians amongst the Greeks and Romans, that though heaven, earth, hell, and all the elements, were filled with divinities, there was yet one who, whether called Jove, Osiris, Ormuzd, or by any other title, was considered as supreme over all the rest. "Whence each of the gods

---

[1] Divine Legation, book iv. sect. 4.

[2] To prove that it was merely to preserve and increase the breed of useful animals in Egypt, that the prince and the priest first taught the people to consider such animals as sacred, he argues thus: "Hæc ita esse, non ex eo tantum liquet, quod paulo ante observavi, nullas bestias universo Ægyptiorum populo sacras fuisse, præter eas, quæ manifestam regioni utilitatem comparent; sed inde quoque apparet, quod longe major ratio habita fuit famellarum inter animalia, quam marium. Boves diis immolare licebat, vaccas nullo modo. Canes fœminæ contumulabantur, non item mares."

Theogony.

was generated," says Herodotus,[1] "or whether they have all existed from eternity, and what are their forms, is a thing that was not known till very lately; for Hesiod and Homer were, as I suppose, not above four hundred years my seniors; and these were they who introduced the theogony amongst the Greeks, and gave the gods their several names." Now Hesiod,[2] towards the beginning of his Theogony, expressly invokes his muse to celebrate in suitable numbers the generation of the immortal gods who had sprung from the earth, the dark night, the starry heavens, and the salt sea. He calls upon her likewise to say, "in what manner the gods, the earth, the rivers, ocean, stars, and firmament, were generated, and what divine intelligences had sprung from them of benevolent dispositions towards mankind." From this invocation, it is evident that the poet did not consider the gods of Greece as self-existent beings. Neither could he look upon them as creatures; for of creation the ancient Greeks had no conception (see the article METAPHYSICS); but he considered them as emanations coeval with the earth and heavens, from some superior principles; and by the divine intelligences sprung from them, there cannot be a doubt but that he understood benevolent dæmons. The first principles of all things, according to the same Hesiod, were Chaos, and Tartarus, and Love, of which only the last being active, must undoubtedly have been conceived by this father of Grecian polytheism to be the greatest and only self-existing god. This, we say, must undoubtedly have been Hesiod's belief, unless by Tartarus we here understand a self-existent principle of evil; and in that case his creed will be the same with that of the ancient Persians, who, as we have seen, believed in the self-existence of Ahriman as well as of Ormuzd.

Hesiod is supposed to have taken his theology from Orpheus; and it is evident that his doctrine concerning the generation of the gods is the same with that taught in certain verses[3] usually attributed to Orpheus, in which Love and Chaos are thus brought together. "We will first sing," says the poet, "a pleasant and delightful song concerning the ancient Chaos, how the heavens, earth, and seas were formed out of it; as also concerning that all-wise Love, the oldest and self-perfect principle, which actively produced all these things, separating one from another." In the original passage, Love is said to be not only πολυμητις, of much wisdom or sagacity, and therefore a real intelligent substance; but also to be πρεσβυτατος and ἀυτοτελης, the oldest and self-perfect, and therefore a being of superior order to the other divinities, who were generated together with the elements over which they were conceived to preside.

With the theology of Homer our readers of all descriptions are so well acquainted, that we need not swell the article with quotations to prove that the father of epic poetry held Jove to be the father of gods and men. But the doctrine of the poets was the creed of the vulgar Greeks and Romans; and therefore we may conclude that those nations, though they worshipped gods and lords innumerable, admitted but one, or at the most two, self-existent principles, the one good and the other evil.[4] It does not indeed appear that in the system of vulgar paganism the subordinate gods were accountable to their chief for any part of their conduct, except when they transgressed the limits of the provinces assigned them. Venus might conduct the amours of heaven and of earth in whatever manner she pleased; Minerva might communicate or withhold wisdom from any individual with or without reason; and we find, that in Homer's battles the gods were permitted to separate into parties, and to support the Greeks or Trojans, according as they favoured the one or the other nation. Jove indeed sometimes called them to order; but his interference was thought partial, and an instance of tyrannical force rather than of just authority. The vulgar Greeks, therefore, although they admitted but one, or at most two, self-existent principles, did not consider the inferior divinities as mediators between them and the supreme, but as gods to whom their worship was on certain occasions to be ultimately directed.

Theogon

Creed of the philosophers.

The creed of the philosophers seems to have been different. Such of them as were theists, and believed in the administration of Providence, admitted of but one god, to whom worship was ultimately due; and they adored the subordinate divinities as his children and ministers, by whom the course of Providence was carried on. With respect to the origin of those divinities, Plato is very explicit, where he tells us,[5] that "when all the gods, both those who move visibly round the heavens, and those who appear to us as often as they please, were generated, that God, who made the whole universe, spoke to them after this manner: Ye gods of gods, of whom I myself am father, attend." Cicero teaches the very same doctrine with Plato concerning the gods;[6] and Maximus Tyrius, who seems to have understood the genius of polytheism as thoroughly as any man, gives us the following clear account of that system as received by the philosophers. "I will now more plainly declare my sense by this similitude: Imagine a great and powerful kingdom or principality, in which all agree freely and with one consent to direct their actions according to the will and command of one supreme king, the oldest and the best; and then suppose the bounds and limits of this empire not to be the river Halys, nor the Hellespont, nor the Meotian Lake, nor the shores of the ocean; but the heavens above and the earth beneath. Here, then, let that great king sit immoveable, prescribing to all his subjects laws, in the observance of which consists their safety and happiness. The partakers of his empire being many, both visible and invisible, are gods; some of them that are nearest and immediately attending on him, are in the highest regal dignity, feasting as it were at the same table; others, again, are their ministers and attendants; and a third sort are inferior to them both: And thus you see how the order and chain of this government descends down by steps and degrees from the Supreme God to the earth and men." In this passage we have a plain acknowledgement of one Supreme God, the sovereign of the universe, and of three inferior orders of gods, who were his ministers in the government of the world; and it is worthy of observation, that the same writer calls these intelligences θεους, θεου παιδας και φιλους, gods, the sons and friends of gods. He likewise affirms, that all ranks of men, and all nations on earth, whether barbarous or civilized, held the same opinions respecting one Supreme Numen, and the generation of the other gods.

[1] Lib. ii. c. 51.

[2] Vers. 104–112.

[3] *Argonautica*, p. 17, edit. Steph.

[4] Plutarch is commonly supposed, and we think justly, to have been a believer in two self-existent principles, a good and an evil. His own opinion, whatever it was, he declares (*de Iside et Osiride*) to have been most ancient and universal, and derived from theologers and lawgivers, by poets and philosophers. "Though the original author of it be unknown, yet," says he, "it has been so firmly believed everywhere, that traces of it are to be found in the sacrifices and mysteries both of the barbarians and the Greeks. There is a confused mixture of good and evil in everything, and nothing is produced by nature pure. Wherefore it is not one only dispenser of things, who, as it were, out of several vessels, distributes these several liquors of good and evil, mingling them together, and dashing them as he pleases; but there are two distinct and contrary powers or principles in the world, one of them always leading, as it were, to the right hand, but the other tugging the contrary way. For if nothing can be made without a cause, and that which is good cannot be the cause of evil, there must needs be a distinct principle in nature for the production of evil as well as good."

That this is palpable Manicheism appears to us so very evident as to admit of no dispute. It appeared in the same light to the learned Cudworth; but that author labours to prove that Plutarch mistook the sense of Pythagoras, Empedocles, Heraclitus, Anaxagoras, and Plato, when he attributed to them the same opinions which were held by himself. Mosheim, on the other hand, has placed it beyond a doubt, that whatever was Plutarch's belief respecting the origin of evil, and the existence of two independent principles, it was taken implicitly from the writings of Plato. But the chancellor of Göttingen, actuated by the same motives with Cudworth, wishes to persuade his readers that by Plato and Plutarch nothing active was understood by their evil principle, but only that tendency to confusion which was then deemed inseparable from matter. But that something more was meant seems undeniable. For immediately after the words which we have quoted, Plutarch proceeds to affirm that the wisest men declare θεους ἐιναι δυο καθαπερ ἀντιτεχνους, "that there are two gods, as it were, of contrary trades or crafts," of which one is the author of all good and the other of all evil. See Mosheim's edition of Cudworth's Intellectual System, lib. i. cap. 4, § 13.

[5] *Timæus.*

[6] *Tusc. Quest.* lib. i. c. 29, and *De Nat. Deorum*, passim.

"If," says he, "there were a meeting called of all these several professions, a painter, a statuary, a poet, and a philosopher, and all of them were required to declare their sense concerning *the god;* do you think that the painter would say one thing, the statuary another, the poet a third, and the philosopher a fourth? No; nor the Scythian neither, nor the Greek, nor the Hyperborean. In other things we find men speaking very discordantly, all men as it were differing from all. But amidst this war, and contention, and discord, you may find everywhere, throughout the whole world, one uniform law and opinion, that there is ONE GOD, THE KING AND FATHER OF ALL, and many gods, the sons of God, who reign with God. These things both the Greek and the barbarian affirm, both the inhabitants of the continent and of the sea-coast, both the wise and the unwise."[1]

Creed of the Brahmins.

This account of philosophical polytheism receives no small support from the Asiatic Researches of Sir William Jones. "It must always be remembered," says that accomplished scholar, "that the learned Indians, as they are instructed by their own books, acknowledge only one Supreme Being, whom they call *Brahm*, or the Great One, in the neuter gender. They believe his essence to be infinitely removed from the comprehension of any mind but his own; and they suppose him to manifest his power by the operation of his divine spirit, whom they name *Vishnu*, the pervader, and *Nérâyan*, or moving on the waters, both in the masculine gender; whence he is often denominated the *first male*. When they consider the divine power as exerted in creating or giving existence to that which existed not before, they call the deity *Brahma;* when they view him in the light of destroyer, or rather changer of forms, they give him a thousand names, of which Siva, Iswara, and Mahadeva are the most common; and when they consider him as the preserver of created things, they give him the name of Vishnu. As the soul of the world, or the pervading mind, so finely described by Virgil, we see Jove represented by several Roman poets; and with great sublimity by Lucan in the well-known speech of Cato concerning the Ammonian oracle, 'Jupiter is wherever we look, wherever we move.' This is precisely the Indian idea of Vishnu; for since the power of preserving created things by a superintending providence belongs eminently to the godhead, they hold that power to exist transcendently in the preserving member of the triad, whom they suppose to be *everywhere always*, not in substance, but in spirit and energy." This supreme god Brahm, in his triple form, is therefore the only self-existent divinity acknowledged by the philosophical Hindus. The other divinities are all looked upon either as his creatures or his children, and of course are worshipped only with inferior adoration.

Why the philosophers worshipped the inferior divinities.

It was upon this principle of the generation of the gods, and of their acting as ministers to the Supreme Numen, that all the philosophers of Greece, who were not atheists, worshipped many divinities, though they either openly condemned or secretly despised the traditions of the poets respecting the amours and villanies of Jupiter, Venus, Mercury, and the rest of the tribe. It was the same principle sincerely admitted, and not an ill-timed jest, as has been absurdly supposed, that made Socrates, after he had swallowed the poison, request his friend to offer a votive cock for him to Æsculapius.

But a theogony was not peculiar to the Greeks, Romans, and the Hindus; it formed part of every system of polytheism. Even the Egyptians themselves, the grossest of all idolaters, believed in one self-existing God, from whom all their other divinities descended by generation. This appears probable from the writings of Horus Apollo, Jamblicus, Porphyry, and many other ancient authors; but if the inscription on the gates of the temple of Neith, in Sais, as we have it from Plutarch and Proclus, be genuine, it will admit of no doubt. This famous inscription, according to the last of these writers, was to this purpose: "I am whatever is, whatever shall be, and whatever has been. My veil no man has removed. The offspring which I brought forth was the Sun."[2]

The Persian Magi, as we have seen, believed in two self-existent principles, a good and an evil. But if Diogenes Laertius deserves to be credited, they held that fire, earth, and water, which they called gods, were generated of these two. It was observed in the beginning of this article, that the first object of idolatrous worship was probably the sun, and that this species of idolatry took its rise in Chaldæa or Persia. But when it became the practice of eastern monarchs to conceal themselves wholly from their people, the custom, as implying dignity, was supposed to prevail in heaven as well as on earth; and Zoroaster, the reformer of the Persian theology, taught,[3] that "Ormuzd was as far removed from the sun as the sun is removed from the earth." According to this modification of Magianism, the sun was one of the generated gods, and held the office of prime minister or vicegerent to the invisible fountain of light and good. Still, however, a self-existent principle of evil was admitted; but though he could not be destroyed or annihilated by any power, it was believed that he would at last be completely vanquished by Ormuzd and his ministers, and rendered thenceforward incapable of producing any further mischief.

Vulgar polytheists less culpable than the philosophers.

From this short view of polytheism, as we find it delineated by the best writers of antiquity, we think ourselves warranted to conclude that the whole pagan world believed in but one, or at most two, self-existent gods, from whom they conceived all the other divinities to have descended in a manner analogous to human generation. It appears, however, that the vulgar pagans considered each divinity as supreme and unaccountable within his own province, and therefore entitled to worship which rested ultimately in himself. The philosophers, on the other hand, seemed to have viewed the inferior gods as accountable for every part of their conduct to him who was their sire and sovereign, and to have paid to them only that inferior kind of devotion which the church of Rome pays to departed saints. The vulgar pagans were sunk in the grossest ignorance, from which statesmen, priests, and poets, exerted their utmost influence to keep them from emerging; for it was a maxim which, however absurd, was universally received, that "there were many things true in religion,[1] which it was not convenient for the vulgar to know; and some things which, though false, it was yet expedient that they should believe." The polytheism and idolatry of the vulgar, therefore, were their misfortune rather than their fault. But the philosophers were wholly "without excuse;[2] because that when they knew God, they glorified him not as God, neither were thankful, but became vain in their imaginations, and their foolish heart was darkened. Professing themselves wise, they became fools, and worshipped and served the creature more than the Creator, who is God blessed for ever." (H. H. H. H.)

[1] *Dissert.* i.

[2] Τα ὀντα, και τα ἐσομενα, και τα γεγονοτα, ἐγω εἰμι. Τον ἐμον χιτωνα ουδεις ἀπεκαλυψεν. Ὁν ἐγω καρπων, ἡλιος ἐνενετο. The antiquity of this inscription is admitted by Cudworth, denied by Mosheim, and doubted by Jablonski. The reader who wishes to know their arguments may consult Mosheim's edition of the Intellectual System, and Jablonski's *Pantheon Ægyptiorum.*

[3] Plutarch, *de Iside et Osiride.*

POMBAL, a city of Portugal, in the province of Estremadura, and the corregimiento of Leiria. It stands on a hill, near to which are the striking ruins of an ancient castle. It contains but one church, which is much frequented by pilgrims as well as by inhabitants, on account of a supposed holy image to which miraculous virtue is ascribed. Pombal has 860 houses, with about 4000 inhabitants, some of whom are employed in making hats. The most celebrated, or, according to some, the most profligate, statesman of Portugal, long at the head of the ministry, took his title of marquis from this place.

POMERANIA, a province of Prussia, extending along the southern shore of the Baltic Sea, from long. 12. 29. to 17. 51. It is bounded on the east by West Prussia, on the south by Brandenburg, and on the west by the duchies of Mecklenburg-Schwerin and Mecklenburg-Strelitz. It extends over 12,450 square miles, but in it are included several lakes and extensive estuaries, called *Haffs*, which occupy more than one tenth of the whole surface. Pomerania was an independent duchy until 1637, when, by the death of the reigning prince, it descended to the elector of Brandenburg; but as, during the life of that prince, in the course of the thirty years' war, Sweden had possessed itself of the eastern part of Pomerania, including the island of Rugen and the city of Stralsund, it retained that portion till, by the treaty of 1815, the Swedish territories in Germany were ceded to Prussia, in consideration of that state having guaranteed the cession of Norway to Sweden. It was formerly divided into East and West Pomerania, the river Oder being the line of division between them; but since the whole has been under the Prussian king, it has been formed into three provincial governments, namely, Stettin, Stralsund, and Koslin. By the census of 1817 the population amounted to 689,486, and by that of 1826 it had increased to 846,722. Of these, 16,700 were military, 6700 Catholics, and 4170 Jews; the remainder were Protestants.

The whole province is a continued plain, mostly a sandy soil, covered with heaths, and occasionally with pines, and intermixed with numerous lakes of different dimensions. There are but few elevations of one hundred feet, and only one, near Koslin, which exceeds two hundred feet. The greater portion of the soil is far from fruitful, and barely produces sufficient grain and potatoes for the subsistence of the inhabitants. The chief corn is rye; very little wheat is raised; and the quantity of barley is much less than of oats. There are, however, on the banks of the Oder, and on those of some of its tributary streams, strips of land of such natural fertility as to afford good grass, both for fodder to cattle, and also for making butter and cheese. The manufactures are of the domestic kind, and mostly upon a contracted scale. The chief occupation is spinning flax, in which all females and many males are employed during the long winter evenings. Some coarse woollen cloths are made; and the breweries and distilleries are numerous. On the coast there are several of the town's establishments for building vessels of various descriptions. The climate in winter, though occasionally very cold, may be more properly described as variable, having severe frosts alternating with sudden thaws; but the unexampled increase of the population seems to show that it cannot be an insalubrious district.

POMFRET, JOHN, an English poet, son of the rector of Luton, in Bedfordshire, was born in 1667, and educated at Cambridge; after which he took orders, and was presented to the living of Malden, in Bedfordshire. About 1703 he went to London for institution to a larger and more considerable living; but he was stopped for some time by Compton, then bishop of London, on account of four lines of his poem entitled the Choice.

> And as I near approach'd the verge of life,
> Some kind relation (for I'd have no wife)
> Should take upon him all my worldly care,
> While I did for a better state prepare.

The parenthesis in these lines were so maliciously represented, that the good bishop was made to believe that Pomfret preferred a mistress to a wife. But he was soon convinced that this representation was the mere effect of malice, as Pomfret at that time was actually married. The opposition which his slanderers had made to him, however, produced its effect; for, being thereby obliged to stay in London longer than he intended, he caught the small-pox, and died of this disease at the age of thirty-five.

He published, in 1699, a volume of his poems with a very modest and sensible preface. Two pieces of his were published after his death by his friend Philalethes; one entitled Reason, and written in 1700, when the disputes about the Trinity ran high; and the other *Dies Novissima*, or the Last Epiphany, a Pindaric ode. His versification is not unmusical, but his writings want that force which is necessary to constitute a poet. A dissenting teacher of his name, and who published some rhymes upon spiritual subjects, subjected him to the imputation of fanaticism; but his friend Philalethes has vindicated him from that charge. Pomfret had a very strong tincture of devotion, but no fanaticism, in his composition.

"The Choice," says Dr Johnson, "exhibits a system of life adapted to common notions, and equal to common expectations; such a state as affords plenty and tranquillity, without exclusion of intellectual pleasures. Perhaps no composition in our language has been oftener perused than Pomfret's Choice. In his other poems there is an easy volubility; the pleasure of smooth metre is afforded to the ear, and the mind is not oppressed with ponderous or entangled with intricate sentiment. He pleases many; and he who pleases many must have merit."

POMME, or POMMETTE, in *Heraldry*, is a cross having one or more balls or knobs at each of the ends.

POMMEL, or PUMMEL, in the *Manège*, a piece of brass or other matter at the top and in the middle of the saddle-bow.

POMŒRIUM, in Roman antiquity, was, according to Livy, that space of ground, both within and without the walls, which the augurs, at the first building of cities, solemnly consecrated, and on which no edifices were allowed to be raised. Plutarch gives this account of the ceremony of drawing the pomœrium: "They dug a trench, and threw into it the first-fruits of all things, either good by custom, or necessary by nature; and every man taking a small turf of earth of the country from whence he came, they cast them in promiscuously. Then making this trench their centre, they described the city in a circle round it. After this, the founder, yoking a bull and a cow together, ploughed a deep furrow, with a brazen ploughshare, round the bounds. The attendants took care that all the clods fell inwards, that is, toward the city. This furrow they called *Pomœrium*, and built the wall upon it." In this account Plutarch is to be understood as speaking of Rome.

---

[1] Varro apud D. Augustinum *de Civitate Dei.*

[2] Romans, i. 20, 21, 22, 25.

POMPEII, an ancient city of Italy, situated in that part of the country to which the ancients gave the name of Campania. It lies at the bottom of the Gulf of Cumæ, known in modern times as the Bay of Naples, five miles from the volcanic mountain of Vesuvius, and thirteen miles south-east of the city of Naples. Pompeii was in no particular manner distinguished for its magnificence or its historical renown; but the destiny which overtook it, as remarkable as it is happily rare, renders it one of the most interesting spots on the face of the globe. Near the commencement of the Christian era it was overwhelmed by a deluge of ashes, water, and mud, discharged from the neighbouring volcano; and, after lying buried for about seventeen centuries, its streets and houses, with its temples and theatres, have again been laid open to the light of day, and retraversed by the busy foot of man.

Of the early history of Pompeii little is known. It is said to have been founded by Hercules, and that its name is derived from Pompa, in allusion to the pomp with which that hero celebrated his victories whilst awaiting his fleet at the mouth of the river Sarnus, after his reputed conquest of Spain. This refuge in mythology, to which men have betaken themselves in accounting for the origin of Pompeii, is a sufficient proof that the obscurity in which it is hidden is too profound to be penetrated. Strabo, however, asserts that these towns were founded by Pelasgians and Tyrrhenians; and this statement is by no means destitute of plausibility. We may indeed conclude, with some degree of confidence, that the foundations of Pompeii were laid long before those of Rome itself. The early history of the city is nearly as uncertain as the date of its foundation and the etymology of its name. It is first mentioned in the account of the Social or Marsic War, which broke out ninety-one years before the birth of Christ, as one of the towns of Campania that had revolted. It escaped the punishment with which some other places were visited; and the only subsequent event of any moment which is related of it, is a quarrel between its inhabitants and those of Nuceria, now Nocera, in which the latter were worsted.

This transaction occurred A. D. 59. Four years afterwards, Pompeii was almost destroyed by an earthquake, the terrible effects of which are recorded by Seneca. A great part of the town was reduced to ruins; and Herculanum was likewise considerably injured. Similar alarms, the usual presages of an approaching eruption, were repeated, until the memorable 23d of August A. D. 79, when the first recorded volcanic paroxysm of Vesuvius occurred. We are fortunately in possession of a faithful and striking narrative of the event, contained in two letters of Pliny the younger to Tacitus. He was an eye-witness of the catastrophe, and, besides a description of it, he gives an account of the death of his uncle, who fell a victim to his inquiring spirit and humanity.

It was not lava, but showers of stones, cinders, and mud, which overwhelmed Pompeii; pouring down for more than a week, and much of the matter having been deposited in a liquid state. Nor was it by one eruption alone that the cities were covered to their present depth. Successive layers are clearly to be traced, and the lowest bears marks of having been moved, whilst the others are untouched; a plain proof that some time elapsed between their deposition, and that the inhabitants had made excavations in search of their more valuable property. The bed of ashes and stones which covered Pompeii varied in depth from twelve to fourteen feet. Under this it remained for one thousand six hundred and seventy-six years; for although indications of its ruins were observed in 1689, the excavations did not commence till 1755. The disappointment experienced on the failure of the attempt to excavate Herculanum to any extent has thus been compensated; for whilst the thick layers of lava which covered the latter city rendered the undertaking too difficult to be persevered in, the light friable mass which entombed Pompeii was easily removed. The upper stories of the buildings, which were probably composed of wood, were either burned by the red-hot matter which fell upon them, or forced inwards by the weight of the enormous superincumbent mass, or the violence with which it descended. With this exception, we see a beautiful and once flourishing city, just as it existed nearly eighteen centuries ago. The buildings stand as they were originally designed, unviolated by time or fashion; the paintings are as fresh as if they had newly come from the easel; and, in some instances, memorials of a more impressive character bear sad testimony to the suddenness and completeness of the calamity which overwhelmed the city.

Pompeii was originally situated upon the sea-shore, as is proved by shells and sea-sand being found on the side adjoining the Bay of Naples; and it is even said that rings have been discovered close to the ruins, intended, as is supposed, for the mooring of vessels. By the gradual elevation of the coast, it is now at some distance inland; and the river Sarnus, which, it is not improbable, was once capable of receiving the vessels of the ancients, has shrunk to a mere rivulet, and is diverted from its original course. The city stood on an insulated spot formed by the lava which, at some remote period, the action of subterranean fire seems to have thrown up in various directions around the foot of Vesuvius. Thus situated, it combined all the advantages of mercantile convenience with the security of a military station, and the romantic beauty of a spot celebrated in all ages for its surpassing loveliness, and which was a favourite resort of strangers for health or recreation. The city was surrounded by a wall, the whole, or nearly the whole, of which has been traced; and six gates and twelve towers have been counted. Its greatest length is little more than three quarters of a mile, its breadth is less than half a mile, and its circumference is nearly two miles. Its general figure is irregularly oval, and it occupied an area of about one hundred and sixty-one acres. There have been excavated above eighty houses, an immense number of small shops, the public baths, two theatres, two basilicæ, eight temples, the prison, the amphitheatre, and other public buildings, besides fountains and tombs. The streets are paved with large irregular pieces of lava, neatly dovetailed into one another. This pavement had been deeply rutted by the chariot-wheels which formerly rattled over it. In general, the streets are so narrow that they may be crossed at one stride. Where they were of greater breadth, a stepping-stone was placed in the middle, it is supposed for the convenience of foot-passengers. On each side there is a foot-path, along which run curb-stones to prevent the encroachments of the biga or chariot. From the position of the town, and the discoveries made by the excavators, it seems clear that only three principal roads could have led to it. The first, which was on the western side, led to Naples; the second joined the Popilian way at Nola; and the third crossed the Sarnus, and afterwards divided into two branches, of which the principal led to Nocera, and the other to Stabia. The city is generally approached by the first road, because it was the ancient route from Rome to Herculanum, and the chief entrance of Pompeii. The first object of interest met with is the Street of Tombs, now completely excavated, which rises by an easy ascent to the city-gate, called the Gate of Herculanum. The road is flanked by tombs of much beauty and interest, as well as by other buildings, amongst which is a hostelry. We quote the following description of Pompeii, as entered by this gate, from an interesting work on the subject. "On entering, the visiter finds himself in a street running a little east of south, which leads to the Forum. To the right stands a house formerly owned by a musician, to the left a *thermopolium* or shop for hot drinks; beyond is the house of the vestals, beyond this the custom-house, and a little further on, where another street runs into this one from the north, at a very acute angle, stands a public fountain. In the last-named street is a surgeon's house, at least one so named from the quantity of surgical instruments found in it, all made of bronze. On the right or western side of the street by which we entered, the houses are built on the declivity of a rock, sloping down to where the sea formerly came, and are several stories in height. The fountain is about one hundred and fifty yards from the city-gate. About the same distance further on, the street divides into two, the right-hand turning seems a by-street, the left-hand turning conducts you to the Forum. The most important feature in this space is a house called the house of Sallust, or of Actæon, from a painting in it representing that hunter's death. It stands on an area about forty yards square, and is encompassed on three sides by streets, by that, namely, which we have been describing, by another nearly parallel to it, and by a third perpendicular to these two. East of this island of houses is an unexcavated space, beyond which is another broad street, running parallel to the first, the limit of the excavations in this quarter. Between these two are indications of another street, which is cleared out, south of the transverse street. Still further south these streets all terminate in a transverse street. Thus the whole quarter already described is divided by four longitudinal and two transverse streets, into what the Romans called islands, or insulated masses of houses. One of these is entirely occupied by the house of Pansa, which, with its court and garden, is about a hundred yards long by forty wide. The average interval between the western and eastern street is not more than a hundred and fifty yards. The island immediately east of the house of Pansa has three houses of considerable interest, called the house of the tragic poet, from dramatic paintings on the walls; the cloth-dyer's house, from paintings illustrating the processes and utensils of that trade; and the house of the mosaic fountains.

"From the transverse street which bounds these islands on the south, two streets lead to the corners of the Forum; between them are the baths, occupying nearly the whole island. Among other buildings are a milk-shop and gladiatorial school. At the north-east corner of the Forum was the triumphal arch. At the end of the broad eastern street, and higher up in the same street, another triumphal arch is still to be made out, so that this was plainly the way of state into the city. The Forum was distant from the gate of Herculanum about four hundred yards. Near the south-eastern corner two streets enter it, one running to the south, the other to the east. We will follow the former for about eighty yards, when it turns eastward for two hundred yards, and conducts us to the quarter of the theatres. The other street, which runs eastward from the Forum, is of more importance, and is called the Street of the Silversmiths.... The quarter of the theatres comprises a large temple of Hercules, a temple of Isis, a temple of Æsculapius, two theatres, and two spacious porticoes enclosing open areas. On the north and east it is bounded by streets; to the south and west it seems to have been enclosed partly by the town, partly by its own walls. Here the continuous excavation ends, and we must cross nine yards to the amphitheatre, distant from the theatre about five hundred and fifty yards, in the south-east corner of the city, close to the walls, and in an angle formed by them. On the other side are traces of walls, supposed to have belonged to cattle-markets. Near at hand a considerable building, called by the Italians the palace of Giulia Felice, has been excavated and filled up again. A considerable distance to the westward is the first excavation, made near the centre of the city; it is surrounded by vines, which hang in festoons from the poplars on which they are trained; it is small, and appears to have been abandoned on account of the few coins and vessels discovered. From the amphitheatre we return along the Street of Silversmiths towards the Forum; but, before we arrive at the latter, turn up a street running parallel to it. Arriving at the end of it, we turn to the right, and soon reach the triumphal arch of the Forum, having now traversed the whole excavated portion, except a few insignificant streets."

Forum. This account of the general aspect of Pompeii renders it less necessary to give any description of particular places and buildings. The Forum was the focus of business, the resort of pleasure, and the scene of all political and legal contention. Entering at the gate of Herculanum, the main street of the town leads the visiter to the north-west corner. Here he gains admittance by a flight of steps leading downwards through an arch in a brick-wall. Upon entering, the spectator finds himself in a large area surrounded by columns and the ruins of temples, triumphal arches, and other public buildings, the particular uses of which can in general be only conjectured. There are also a number of pedestals, which once supported statues; and around the west, south, and east sides, there runs a Doric colonnade in the Grecian style. At the end by which the place is entered stands a building, called by some the temple of Jupiter, and by others the Senaculum or council-chamber. It is prostyle, and of the Corinthian order, and stands upon an elevated basement, which was ascended by a flight of steps. Those near the columns, which served for ornament, and also for supporting the upper part of the building, run along the whole front of the portico. The interior had been painted; red and black are the prevailing colours. Fragments of a colossal statue, and a sun-dial, were discovered. Near this temple are the ruins of what has been conjectured to have been the granary. Adjacent to this building is the prison, where were found the skeletons of two men, their leg-bones still within the shackles. On the opposite side of the temple of Jupiter stands an edifice, which has been called the Pantheon, from its having had in the centre of its area an altar encircled with twelve pedestals, and which, it is supposed, once supported statues of the aristocracy of Italian mythology. The area is a hundred and twenty feet in length by ninety feet in breadth. To this building are attached numerous cells, in all probability for the accommodation of priests. Near to this building were discovered ninety-three brass coins and statues of Nero and Messalina.

On the northern side of the Pantheon there runs a street named the Street of Dried Fruits, from the quantity of fruits of various kinds preserved in glass vases which have been found in it. Scales, money, and moulds for pastry and bread, were discovered in the shops; and a bronze statue of Fame was also found. On the western side of the Forum are the Basilica, a temple supposed to have been dedicated to Venus, and the granary and prison already noticed. The Basilica, or court of justice, is the largest building in Pompeii. It is of an oblong form, two hundred and twenty feet in length by eighty feet in breadth, and corresponds in some particulars with the ancient description of that building. The temple of Venus is the only remaining building of importance connected with the Forum. It possessed the usual apartments, in one of which was found a painting of Bacchus and Silenus in a state of perfect preservation. In most of the paintings the colours are as vivid as when they were first laid on.

Amongst other objects of interest there is a broad street, which, from various articles of jewellery having been found there, is called the Street of the Silversmiths. On the walls of the shops several inscriptions appear, one of which has been thus translated: "The scribe Issus beseeches Marcus Cerrinius Vatia, the ædile, to patronise him; he is deserving." At the end of this street was discovered a skeleton, supposed to have been that of a priest of Isis. In the hand was a bag of coarse linen, not entirely destroyed, containing three hundred and sixty silver coins, forty-two of copper, and six of gold. Near him were also found various articles belonging to the worship of Isis.

Baths.

The baths of Pompeii were excavated in the year 1824. They surpass all the other buildings of Pompeii in magnificence, decoration, good taste, arrangement, and the state of preservation in which they remain. They occupy a considerable space, and are divided into three separate compartments; one was for fire-places and for the use of servants, another was for the men, and a third for the women. The walls of the *frigidarium* are ornamented with figures, and the apartment is round, and altogether remarkable for its beauty. The basin is twelve feet ten inches in diameter, and two feet nine inches deep, and is entirely lined with white marble. The *tepidarium* is divided into a number of compartments, and has also been highly ornamented. The ceiling is adorned with figures and carvings in stucco. In the bronze frame of the window were four beautiful panes of glass, from which it is evident that windows of glass were in use amongst the ancients. Glass-blowing seems to have been better understood by them than many of the learned are inclined to admit. This is proved by the quantities of bottles, vases, glasses, and other utensils made of the same material, which have been discovered in this subterranean city. The *caldarium*, the third and last description of bath made use of by the Romans, is an apartment in all respects as highly finished and decorated as the others.

Theatres.

Two theatres have been excavated in Pompeii, a large one and a small one; both displaying the remains of considerable magnificence. They are constructed after the usual plan of a Roman theatre, and need not therefore be described here. In the large theatre there must have been sufficient space for five thousand persons. This theatre appears to have been entirely covered with white marble, although only a few fragments remain. The other theatre nearly resembles the one here mentioned, but is much smaller, and appears from an inscription to have been permanently roofed.

Adjoining the theatres there is an edifice which, from the style of its architecture, has been called the Greek temple, or the temple of Hercules. It is supposed by some to be of great antiquity, and is in a very dilapidated state. In this quarter also is situated the temple of Isis. It is also one of the most perfect examples now extant of the parts and disposition of an ancient temple. In one of the rooms was found the skeleton of a priest. Near his remains lay an axe, from which it would appear that he had delayed his departure till the door was choked up with the falling ashes, and so had attempted to force his way through the walls with the hatchet. He had already penetrated through two, but before he could break through the third, death arrested his flight. A number of other skeletons were here found, and also some paintings of the priests of Isis, together with a statue of the deity herself. In this neighbourhood stands the temple of Æsculapius, where were found three terra-cotta statues of Æsculapius, Hygeia, and Priapus. Near this is one of the most interesting buildings discovered in Pompeii, not for its beauty, but for its contents, which prove it to have been the abode of a sculptor. There were found statues, some half finished, others just begun, with blocks of marble, and all the tools required by the artist, as mallets, compasses, chisels, saws, and the like. The amphitheatre, which has been excavated, does not differ from other Roman buildings of the same kind. It was calculated to contain ten thousand persons.

Various utensils found.

In a street which conducts to the Forum, and is called the Street of Fortune, an immense number of utensils have been found. Amongst these were vases, basins with handles, bells, elastic springs, hinges, buckles for harness, a lock, an ink-stand, gold ear-rings, a silver spoon, an oval caldron, a sauce-pan, a mould for pastry, a number of lamps (about one thousand were found at the baths), and three boxes with a slit to admit money, one of which contained coins of Titus Vespasian and other Roman emperors. Here also were found seven glazed plates packed in straw, a pair of scales, and a steelyard. In other parts of the city were discovered fishing-nets, some of them quite entire, and linen with the texture well defined. In the shop of a baker there was found a loaf, still retaining its original form, and with the maker's name stamped upon it. On the counter of an apothecary's shop lay a box of pills, and by the side of it was a small cylindrical roll, evidently waiting to be cut up. This mode of administering medicine, therefore, is of very high antiquity. In various parts of Pompeii have been dug up a number of bronze helmets, greaves, and other warlike furniture; more than one candelabrum, braziers of various sorts, vases, cooking vessels and other kitchen utensils, glass vessels, articles of dress, female ornaments, and other articles of luxury.

Skeletons.

But the relics most calculated to interest our feelings are the remains of the human beings who perished in the great catastrophe. A comparatively small number of skeletons have as yet been brought to light; and hence it is clear that most of the inhabitants had found time to make their escape. Besides those already mentioned, there were discovered in the vaults of a house in the suburbs of Pompeii, the skeletons of seventeen individuals, who appear to have sought in vain an asylum there from the tempest of ashes which poured down from the sky. There was likewise preserved in the same place a perfect cast of a woman, supposed to have been the mistress of the house, with an infant locked in her arms. Her form was imprinted upon the consolidated mass in which she was entombed, but of her body only the bones remained. To these a chain of gold was suspended, and rings with jewels were upon the bones of the fingers. The remains of a soldier were found in a niche, where in all probability he was performing the office of sentinel. His hand still grasped a lance, and the other military accoutrements worn at the time were found beside him or upon his bones.

Architecture and houses.

The architecture of Pompeii is not always in the best taste; yet there is much to be admired in it, both for design and execution. At the same time, except in those quarters where the public buildings were situated, there could have been nothing striking or magnificent in the appearance of the city as a whole. The houses were of small height, and externally gloomy; the lower part being usually a blank wall plastered over, and often painted with different colours, and the upper pierced with small windows to light the apartments on the first floor. Internally there is very little costly decoration to be found, with the exception of mosaic pavements, which are numerous and extremely beautiful; and even in the public buildings marble is of rare occurrence. Its place, however, was not inadequately supplied by a stucco of great beauty, equally adapted to receive paintings or to be modelled into bas-reliefs; and these have been found in great abundance. The paintings are in general in a state of perfect preservation, and have all the freshness of recent finishing. In the Pompeian houses every species of masonry described by Vitruvius may, it is said, be met with; but the cheapest and least durable sorts have been generally preferred; and by far the greater part of the private, and many of the public edifices, are built of bricks, or of the rough masonry which is called *opus incertum*. Hence arises their rapid decay on being exposed to air. Copper, iron, lead, and other metals, have been found employed for the same purposes as those for which we now use them, so that the articles discovered need not be enumerated. Almost all the door-ways are nearly of the same size and form, a little more or less care in the execution of capitals and entablatures making all the difference between them. It is rare in Pompeii to see a whole house set apart for purposes of trade, a portion of it almost invariably furnishing an abode for the owner. The houses of the richer classes were usually surrounded by shops. Throughout the streets numerous signs are to be seen upon the shops, indicative of the trades which were pursued within. One of these represents two men carrying an amphora, and probably served as the sign of a wine-shop. And there is a painting of a boy mounted upon the back of another, and undergoing a process of flagellation; an ominous indication to all idlers that the schoolmaster was at home.

Fountains, sewers, and tombs.

Fountains are very numerous both in the streets and houses of Pompeii, but it is not known from what source or sources the city was supplied with water. But, however obtained, the waters once brought to the city were distributed to its different quarters by conduits of masonry, lead, or baked earthen pipes. Fountains, which appear to have been *jets d'eau*, have been found in several houses; and there is a painting of one representing a broad vase with a jet of water rising from the centre. Of the manner in which the town was drained, and the numberless impurities carried off, little is known satisfactorily; but remains of a considerable sewer, with minor drainages converging to it, have been observed. The tombs line the approach to the city through the gate of Herculanum. They are numerous, and almost all those which have been found are raised upon a platform of masonry above the level of the footway. They are themselves solid, elegant, and in many instances highly ornamented structures.

Manuscripts.

No perfect manuscripts, nothing but mere fragments, have been found at Pompeii. It may be mentioned, that most of the houses have received their names from the paintings on the walls; but some have been designated from persons of rank being present at their excavation, and from other accidental circumstances. (R. R. R.)

POMPEY THE GREAT, CNEIUS POMPEIUS MAGNUS, the renowned rival of Julius Cæsar. Being defeated at the battle of Pharsalia, owing to the defection of his cavalry, Pompey fled by sea to Egypt, where he was basely assassinated by order of Theodotus, prime minister to Ptolemy the younger, then a minor, 48 B.C. See ROME.

POMPEY's Pillar, vulgarly so called, a celebrated column near Alexandria, in Egypt, 114 feet in height, and of which the shaft, composed of a single piece of granite, is ninety feet.

POMPONATIUS, PETER, an eminent Italian philosopher, was born at Mantua in 1462. He was of so small a stature that he was little better than a dwarf; yet he possessed an exalted genius, and was considered as one of the greatest philosophers of the age in which he lived. He taught philosophy with the highest reputation, first at Padua, and afterwards at Bologna. He had frequent disputations with the celebrated Achillini, whose puzzling objections would have confounded him, had it not been for his skill in parrying them by some joke. His book *De Immortalitate Animæ*, published in 1516, made a great noise. He maintained, that the immortality of the soul could not be proved by philosophical reasons; but solemnly declared his belief of it as an article of faith. This scrimp precaution did not, however, save him. Many adversaries rose up against him, who did not scruple to treat him as an atheist; and the monks caused his book, although he wrote several apologies for it, to be burned at Venice. His work upon Incantations was also thought very dangerous. In it he shows that he believed nothing of magic and sorcery; and he lays a prodigious stress on occult virtues in certain men, by which they produced miraculous effects. Of this he gives a great many examples, but his adversaries do not admit them to be true, or free from magic. Paul Jovius says, that he died in 1525, in his grand climacteric. He was three times married, and had but one daughter, to whom he left a large sum of money. He used to apply himself so very intensely to the solution of difficulties, that he frequently forgot to eat, drink, sleep, and perform the ordinary functions of nature.

PONARUM, a town of the south of India, in the Carnatic, fifty-five miles south-west from Pondicherry. Long. 79. 20. E. Lat. 11. 26. N.

PONDAH, a town and celebrated fortress of Hindustan, in the province of Bejapore, which stands at the foot of the Western Ghauts, and commands the most frequented pass into the interior from Goa and Soondah. It was taken by the Mahrattas under Sevajee in 1673; and being afterwards, in 1683, besieged by the Portuguese, it was relieved by Sambajee, who, observing that they had made greater progress in battering the fortifications in ten days, than his father had done in three months, ordered them to be razed. Long. 73. 56. E. Lat. 15. 23. N.

PONDI, a small island in the Eastern Seas, separated from Madura by a channel a mile in width, with a small bay which affords a safe anchorage for shipping. It is well cultivated, and has a pleasant appearance. Long. 114. 23. E. Lat. 6. 57. S.

PONDICHERRY, a city on the sea-coast of the south of India, in the province of the Carnatic, and once the most splendid city in the East. But it has never recovered from the destruction inflicted on it by the British in 1761. It stands on a sandy plain, not far from the sea-shore, which produces only palm-trees, millet, and a few herbs. It was formerly a village, which, with a slip of land about five miles in length, was purchased by the French from the king of Bejapore in 1672. Under their rule it became a populous and thriving settlement. It was taken by the Dutch in 1693, who improved the town and enlarged the fortifications. It was restored at the peace of Ryswick to the French; and in the course of half a century a handsome and regular town was built, the houses in general being two stories high, with flat roofs, and colonnades in front. The town, thus improved and enlarged, became the capital of the French settlements in the East. Having no natural advantages as a commercial town, when the French were expelled from India it fell into decay. When it was occupied by the British in 1761, the fortifications were completely destroyed, and the ditch was filled up by the earth of the glacis. These devastations were also extended, by the animosity of the Madras government, to the buildings, public as well as private; and it is mentioned by Lord Valentia, that the Jesuits' College, and some of the public buildings, still remain, memorials of their resentment. The private houses, however, have been completely repaired, and the same traveller considers Pondicherry as the handsomest town he had seen in India, with the exception of Calcutta. It is better fitted for a maritime station than Madras, as, during the south-west monsoon, the season of naval warfare, it is to the windward, which was found by the French to be of great advantage during the wars of the last century. In the middle of the square are still seen the pillars and other ornaments of a pagoda of black stone richly ornamented with carving. They remain strewed on the ground, no unfit emblem, Lord Valentia adds, of the fallen power of the French in this country. On the 26th of August Pondicherry was besieged by Admiral Boscawen, who was compelled to raise the siege in the following October, after losing about 1000 Europeans. M. Lally landed at this place in 1758, and succeeded Dupleix as governor, when an action was commenced between the British and the French, which ended in the total ruin of the French power in India, and Pondicherry surrendered to Colonel Coote on the 16th of January 1761. At the peace of 1763 this fortress was restored to the French, with the fortifications in a very dilapidated condition. By the skill of the French engineers the fortifications were repaired and considerably strengthened. In 1778 Pondicherry surrendered to Colonel Munro, after an obstinate defence. At the peace of 1783 it again devolved to the French; and on the breaking out of hostilities surrendered to the British on the 23d of August 1793. It was restored at the peace of Amiens, when the population was estimated at 25,000, and the revenue at 40,000 pagodas. Bonaparte sent out as a garrison 1400 European troops, with a large military staff, in the view, it was supposed, of prosecuting schemes of ambition in India; but whatever were his plans, they were frustrated by the short duration of the peace, and Pondicherry was again occupied by the British in 1803. Pondicherry still continues the capital of the French settlements in India, but is no longer considered as a place of consequence, either politically or commercially. The travelling distance from Madras is 100 miles, from Seringapatam 260, from Hyderabad 452, from Delhi 1400, from Calcutta 1130, from Najpoor 773, from Poonah 707. Long. 74. 0. E. Lat. 18. 30. N.

PONDIMARKA, a seaport of Hindustan, in the Northern Circars, and district of Cicacole, which contains a small bay, only capable of receiving small boats. Long 83. 0. E. Lat. 17. 37. N.

PONDONG, a small island in the Eastern Seas, near the south-east coast of Siao. Long. 125. 10. E. Lat. 2. 40. N.

PONIARD, a little pointed sharp-edged dagger, borne in the hand or at the girdle, or hidden in the pocket. The word is formed from the French *poignard*, and that from *poignée*, handful. The poniard was anciently in constant use; but it is now laid aside, except amongst assassins. Sword and poniard were the ancient arms of duellists, and are said to continue so still amongst the Spaniards. The practice of sword and poniard forms part of the exercise taught by the masters of defence.

PONS, St, an arrondissement of the department of Hérault, in France, extending over 488 square miles. It comprises five cantons, and is divided into forty-four communes, containing 40,160 inhabitants. The capital is the city of the same name, usually distinguished as Saint Pons de Thomiers. It is situated in a valley surrounded by lofty mountains, watered by the river St Jean, and contains 5340 inhabitants, who are occupied partly in cotton-spinning and tanning. Long. 2. 53. E. Lat. 43. 32. N.

PONT-A-MOUSSON, a city of France, in the department of the Meurthe, and the arrondissement of Nancy. It is a neat place, situated in a charming valley, through which flows the river Moselle. It is fortified, and contains four churches, 925 houses, and 6680 inhabitants, who carry on the trades of spinning cotton by machinery, and of tanning leather. Long. 5. 57. 1. E. Lat. 48. 54. 19. N.

PONTARLIER, an arrondissement of the department of the Doubs, in France, extending over 531 square miles. It is divided into five cantons, and these into ninety communes, containing 43,100 inhabitants. The capital is the city of the same name, situated in a mountainous district on the banks of the river Doubs. It contains 640 houses, and 4100 inhabitants.

PONT AUDEMER, an arrondissement of the department of the Eure, in France. It is 390 square miles in extent, and comprehends eight cantons, divided into 143 communes, and has a population of 94,650 persons. The capital is a city of the same name, situated on the river Nille. It is surrounded with walls, stands in a fertile spot, and contains 1450 houses, with 5800 inhabitants, who are employed chiefly in making cotton goods. Long. 0. 31. E. Lat. 49. 22. N.

PONT DE BAUX, a city of France, in the department of the Ain, and arrondissement of Bourg. It is situated on the river Reyssouse, is well built, and contains a hospital, a fine corn-hall, 320 houses, and 3050 inhabitants, who carry on a brisk trade in hemp, flax, corn, and wine, by means of the canal, which leads to the Soane. Long. 4. 47. E. Lat. 46. 25. N.

PONTE-CORVO, a city of Italy, in the papal territory, and province of Frosinone, the see of a bishop, and situated on the banks of the river Garigliano. It contains six churches, and, including a small district, 5600 inhabitants. Bonaparte created Bernadotte prince of Ponte-Corvo.

PONTEFRACT, a market and borough town of the west riding of Yorkshire, in the wapentake of Osgoldcross, and 178 miles from London. It is a corporate town, now governed by a mayor, a recorder, four aldermen, and twelve councillors, and it returns two members to the House of Commons. The soil around it is remarkably fertile, and produces abundance of liquorice-roots, from the juice of which the medicine called pomfret-cakes is made. There are still to be seen ruins of an ancient castle, which is remarkable for the bloody tragedies exhibited within its walls. There Thomas earl of Lancaster was beheaded by Edward II. after the battle of Borough Bridge; Richard II. was long confined in it as a prisoner, and is said to have been murdered there; and the Earl of Rivers and Sir Richard Grey were executed there by order of King Richard III. During the civil wars it was held and ably defended by the party of Charles I., but ultimately taken, and soon afterwards demolished. It is now a well-built town, with a fine market-place and elegant market-cross. The church is a large building. The population of the town amounted in 1801 to 3097, in 1811 to 3605, in 1821 to 4447, and in 1831 to 4832; but the parish, containing five other townships, contained at the last census 9254 inhabitants.

PONTEVICO, a city of Austrian Italy, in the delegation of Brescia, and province of Milan. It is situated on the river Oglio, at the place where the Strone falls into it. It is fortified, and has a castle near it. The inhabitants amount to 5268.

PONTIANA, a Dutch settlement, on a river of the same name, on the western coast of the island of Borneo. It carries on a considerable trade. The imports are piece-goods and opium; the exports diamonds, gold-dust, pepper, and birds' nests. It is situated upon a fine navigable river, nearly under the equator. Long. 109. 30. E. Lat. 3. S.

PONTIFEX, Pontiff, or *High Priest*, a person who has the superintendence and direction of divine worship, as the offering of sacrifices and the celebration of other religious solemnities. The Romans had a college of pontiffs, over which was a sovereign pontiff, or *pontifex maximus*, instituted by Numa, whose function it was to prescribe the ceremonies with which each god was to be worshipped, compose the rituals, direct the vestals, and perform the business of augury, until, on some superstitious occasion, he was prohibited intermeddling therewith. The office of the college of pontiffs was to assist the high priest in giving judgment in all causes relating to religion, inquiring into the lives and manners of the inferior priests, and punishing them if they saw occasion to do so. The Jews, too, had their pontiffs; and amongst the Catholics the pope is styled the *sovereign pontiff*.

PONTIFICATE is used to signify the state or dignity of a pontiff or high priest; but by modern writers it is chiefly applied to the reign of a pope.

PONTIVY, an arrondissement of the department of Morbihan, in France, extending over 632 square miles. It is divided into seven cantons and forty-six communes, and has a population of 90,600 persons. The capital is the city of the same name, situated on the river Blavet, and contains 5100 inhabitants, whose chief trade consists in corn.

PONT L'EVEQUE, an arrondissement of the department of Calvados, in France, extending over 301 square miles, containing five cantons and 135 communes, with 64,350 inhabitants. The capital, a city of the same name, is situated on the river Touques, has a good trade, and contains 510 houses, with 2520 inhabitants. Long. 0. 3. E. Lat. 49. 17. N.

PONTOISE, an arrondissement of the department of the Seine and Oise, in France, extending over 478 square miles, divided into seven cantons and 175 communes, with 87,500 inhabitants. The capital is the city of the same name, situated at the junction of the river Biorne with the Oise. It contains 800 houses, and 5400 inhabitants. The church of St Martin's, a fine Gothic structure, forms its most distinguished ornament. It is celebrated for its veal, which is sent to Paris. Long. 12. 1. E. Lat. 49. 3. N.

PONTOON, in *War*, a kind of flat-bottomed boat, the body of which is composed of wood lined without and within with tin. Pontoons serve for the construction of bridges over rivers, to facilitate military operations. The French pontoons, and those of most other powers, are made of copper on the outside; and though these cost more at first, yet they last much longer than those of tin, and, when worn out, the copper sells nearly for as much as it originally cost; whereas when ours are rendered useless, they sell for nothing. Our pontoons are twenty-one feet in length, five feet in breadth, and in depth within two feet 1·5 inches.

PONTOON-*Carriage* is made with two wheels only, and two long side pieces, the fore ends of which are supported by a limber; and it serves to carry the pontoon, boards, cross-timbers, anchors, and every other thing necessary for making a bridge.

PONTOON-*Bridge* consists of pontoons slipped into the water, and placed about five or six feet asunder, each fastened with an anchor when the river has a strong current; or to a strong rope that goes across the river, running through the rings of the pontoons. Each boat has an anchor, cable-baulks, and chests. The baulks are about five or six inches square, and twenty-one feet in length. The chests are boards joined together by wooden bars, about three feet in breadth and twelve feet in length. The baulks are laid across the pontoons at some distance from one another, and the chests upon them are joined close; which in a very short time makes a bridge capable of supporting any weight.

Etymology of the name.

PONTUS, the name of an ancient kingdom of Asia, originally a part of Cappadocia, and which was bounded on the east by Colchis, on the west by the river Halys, on the north by the Euxine Sea, and on the south by Armenia Minor. Some derive the name of Pontus from the neighbouring sea, commonly called by the ancients *Pontus Euxinus*, and others from an early king named Pontus, who imparted his name both to the country and the sea; whilst Bochart deduces it from the Phœnician word *botno*, signifying a filbert, as if that nut had abounded in the country. But this derivation seems to be very far-fetched; and the common opinion that the country derived its name from the sea seems by far the most probable. The kingdom was divided into three parts; the first named *Pontus Galaticus*, extending from the river Halys to the Thermodon; the second, named *Pontus Polemonaicus*, extended from the Thermodon to the borders of *Pontus Cappadocicus;* and this last, extending from Pontus Polemonaicus to Colchis, had Armenia Minor and the upper stream of the Euphrates for its southern boundary.

Artabazes.

It is commonly believed that the original inhabitants of Pontus were descended from Tubal. In process of time, however, they mixed with Cappadocians, Paphlagonians, and other foreign nations, besides many Greek colonies which settled in those parts, and maintained their liberty till the time of Mithridates the Great and Pharnaces. The first king of this country whom we find mentioned in history is Artabazes, who had the crown bestowed on him by Darius Hystaspes.[1] The next was Rhodobates, who reigned in the time of Darius Nothus. After him came Mithridates, who, having refused to pay the usual tribute to the Persians, was defeated by Artaxerxes Mnemon; but a peace was soon afterwards concluded by the mediation of Tissaphernes. Besides this, we hear nothing farther of him, except that he was treacherously taken prisoner by Clearchus, afterwards tyrant of Heraclea, and obliged to pay a large sum for his ransom.

Mithridates I.

Mithridates I. was succeeded by Ariobarzanes, who being appointed by Artaxerxes governor of Lydia, Ionia, and Phrygia, employed the forces that were under his care in extending his own dominions, and subduing those of his natural prince. The king of Persia sent against him Autophrodates; but Ariobarzanes, having prevailed on Agesilaus, and Timothæus the Athenian, to come to his assistance, obliged Autophrodates to retire. He then rewarded Agesilaus with a large sum of money, and bestowed on Timothæus the cities of Sestos and Abydos, which he had lately taken from the Persians. He used his utmost endeavours to reconcile the Lacedæmonians and Thebans; but not being able to bring the latter to any reasonable terms, he assisted the Lacedæmonians with large sums of money. The Athenians showed so much respect for this prince, that they not only made him free of their city, but granted both to him and to his children whatever they asked. He was murdered in the twenty-eighth year of his reign, by one Mithridates, whom authors suppose to have been his son. This happened at the time when Alexander the Great invaded Asia, so that Pontus for a time fell under the power of the Macedonians.

Mithridates II.

In the reign of Antigonus, Mithridates the son of Ariobarzanes shook off the Macedonian yoke. Antigonus having dreamed that he had a field in which gold grew after the manner of corn, and that Mithridates cut it down and carried it into Pontus, began to be very suspicious of his designs, and ordered him to be put to death privately. But Mithridates, having got notice of the king's intention, withdrew into Paphlagonia, attended only by six horsemen. Here, being joined by many others, he possessed himself of Ciniatum, a stronghold situated near Mount Olgasys, whence, as his army continually increased, he made an irruption into Cappadocia; and having driven the commanders of Antigonus from that part which borders upon Pontus, he entered his paternal kingdom, which, in spite of the utmost efforts of Antigonus, he kept possession of for the space of twenty-six years, and transmitted to his posterity.

Under the reigns of Mithridates III. Ariobarzanes II. and Mithridates IV. the immediate successors of Mithridates II., nothing remarkable occurred. But Mithridates V. made war upon the inhabitants of Sinope, a city on the coast of Paphlagonia. He made himself master of all the adjacent places; but finding the whole peninsula on which Sinope itself stood well fortified and garrisoned, not only by the inhabitants, but also by their allies the Rhodians, he abandoned the enterprise. This prince afterwards proved a great friend of the Rhodians, and assisted them with money to repair the losses which they had sustained by an earthquake. He also entered into a strict alliance with Antiochus the Great, who married one of his daughters, named Laodice.

---

[1] This country, together with the adjacent provinces, was at different periods under the dominion of the Assyrians, Medes, and Persians; the last of whom divided Cappadocia into satrapies or governments, and bestowed that division which was afterwards called Pontus on one of the ancestors of Mithridates. This regulation was effected in the reign of Darius the son of Hystaspes, and has been regarded as the date of the kingdom.

Pharnaces I.

After the death of Mithridates V., his son Pharnaces I., having attacked the city of Sinope, unexpectedly took it by storm. On this the Rhodians sent ambassadors to Rome, complaining of the behaviour of the king of Pontus; but Pharnaces was so far from being intimidated by their threats, that he invaded the territories of Eumenes, their great ally. The latter sent ambassadors to Rome, and entered into an alliance with Ariarathes king of Cappadocia; Pharnaces, in his turn, also sent ambassadors to Rome, complaining of Eumenes and Ariarathes; and their representations being at variance, some Romans were sent into Asia to inquire into the state of matters. These envoys found Eumenes and his associates willing to accommodate the difference, but Pharnaces in a quite opposite disposition, which they accordingly reported at Rome.

In the mean time a war was commenced between Eumenes and Pharnaces; but the latter, being disappointed of assistance from Seleucus king of Syria, whom the Romans would not permit to join him, was at last forced to sue for peace, which was granted him upon certain conditions. It was stipulated that he should forthwith withdraw his forces from Galatia, and disannul all engagements and alliances with the inhabitants of that country; that he should in like manner evacuate Paphlagonia, and send back such as he had from thence carried into slavery; that he should restore to Ariarathes all the places which he had taken during the war, the hostages of both kings, all their prisoners without ransom, and moreover deliver up to them such of their subjects as from the breaking out of the war had fled to him; that he should restore to Morzias, a petty king in these parts, and to Ariarathes, nine hundred talents which he had seized in the war, and pay down three hundred more to Eumenes as a fine for invading his dominions without provocation. Mithridates, king of Armenia, having in this war joined Pharnaces, was, by the articles of the treaty, obliged to pay three hundred talents to Ariarathes for having assisted his enemy, contrary to an alliance at that time subsisting between them. Soon afterwards Pharnaces died, and left the kingdom to his son Mithridates VI. more weakened by this peace than by the most destructive war. The new king entered into an alliance with the Romans, and proved such a faithful friend that he was rewarded by the senate with Phrygia Major, and honoured with the title of the friend and ally of the people of Rome. After a long and prosperous reign, he was murdered by some of his intimate acquaintance, and was succeeded by his son Mithridates VII. surnamed the Great.

Mithridates the Great.

The new prince, though not exceeding thirteen years of age, began his reign with most inhuman acts of cruelty to his mother and nearest relations. His father, by his last will, had appointed him and his mother joint heirs to the kingdom; but he, claiming the whole, threw her into prison, where she soon died in consequence of the hard usage she had met with. Those to whom the care of his education was committed, observing him to be of a cruel and unruly temper, made various attempts on his life; but could never effect their design, as the king was always on his guard, and armed against all kinds of treachery, without showing the least diffidence.

His extraordinary qualities.

In his youth Mithridates took care to inure himself to hardships, passing whole months in the open air, employed in the exercise of hunting, and often taking his rest amidst the frozen snow. When he came of age, he married his sister named Laodice, by whom he had a son named Pharnaces. After this he took a journey through many different kingdoms of Asia, having nothing less in view than the whole continent. He learned their different languages, of which he is said to have spoken twenty-two; took an estimate of their strength; and, above all, viewed narrowly their strongholds and fortified towns. In this journey he spent three years, during which time, a report being spread abroad that he was dead, his wife Laodice had criminal conversation with one of the lords of her court, by whom she had a son. When her husband returned, she presented him with a poisoned bowl; but Mithridates had accustomed himself to take poison from his infancy, so that it had now no other effect than to hasten the destruction of his wife, which soon afterwards took place, together with all those who had been in any way accessory to her disloyalty and incontinence.

His exploits.

The king now began to carry into effect his schemes of conquest. Nothing could be more unwise than to attack those nations which were immediately under the protection of Rome, and thus provoke that powerful people to fall upon him. Beginning with Paphlagonia, which the Romans had declared a free state, he easily reduced this country, which he divided between himself and Nicomedes king of Bithynia, at that time his ally. The Romans remonstrated; but Mithridates, instead of paying any regard to their remonstrances, invaded Galatia, which was immediately under their protection. This he also reduced, and then turned his eyes to Cappadocia. But as the kingdom of Cappadocia was at that time held by Ariarathes, who was a great favourite of the Romans, and married to the sister of Mithridates, the latter hired an assassin to despatch his brother-in-law, after which he thought he might succeed better in his designs. After the death of Ariarathes, Cappadocia was invaded by Nicomedes king of Bithynia, who drove out the son, and married the widow of Ariarathes. This gave Mithridates a plausible pretence for invading Cappadocia, and driving Nicomedes out of that country. Thus he gained considerable reputation, not only as a warrior, but as a just and good-natured prince; for as it was not known that he had had any hand in the murder of Ariarathes, every one conceived that he had undertaken the war against Nicomedes merely to revenge the quarrel of his nephew, and to restore him to his rights. To keep up the farce a little longer, Mithridates actually withdrew his troops from the country, and left the young prince master of the kingdom. In a short time, however, he began to press the young king of Cappadocia to recall the assassin Gordius, who had murdered his father. But this the king of Cappadocia indignantly refused; and Mithridates, being determined on a quarrel at all events, took the field with an army of eighty thousand foot, ten thousand horse, and six hundred chariots armed with scythes.

Assassination of his own nephew.

With this force he imagined he should carry all before him; but finding the king of Cappadocia ready to oppose him with an army not inferior to his own, he had recourse to treachery; and, inviting his nephew to a conference, stabbed him, in the sight of both armies, with a dagger which he had concealed in the folds of his garment. This barbarous and unexpected piece of treachery had such an effect on the Cappadocians that they threw down their arms, and suffered Mithridates, without opposition, to seize upon all their strongholds. The latter, however, resigned the kingdom to his son, a child of eight years of age, and committed to Gordius the care of the young prince and of the whole kingdom; but the Cappadocians, disdaining to be ruled by an assassin, placed on the throne the brother of Ariarathes, who had kept himself concealed in some part of Asia. His reign, however, was of short duration; for being soon afterwards driven out by Mithridates, the Cappadocians were again reduced. The unhappy prince died of grief; and in him ended the family of Pharnaces, who had ruled Cappadocia from the time of Cyrus the Great.

Nicomedes, king of Bithynia, afraid of Mithridates, and supposing that his own dominions would next fall a prey to the ambitious conqueror, suborned a youth of a comely and

Attempt of Nicomedes king of Bithynia to deceive the Romans.

majestic aspect to pretend that he was a third son of Ariarathes, to repair to Rome, and to demand the kingdom of Cappadocia as his just right. He was received by the senate with the greatest kindness; and Laodice, the wife of Nicomedes, confirmed the deceit by her oath. But in the mean time Mithridates, having obtained intelligence of the plot, sent notice of it to the Romans by Gordius, so that the imposture soon became known at Rome. The consequence was, that the senate commanded Mithridates to relinquish Cappadocia, and enjoined Nicomedes to give up that part of Paphlagonia which he possessed, declaring both these countries free. The Cappadocians protested that they could not live without a king, and were allowed to choose one of their own nation. Mithridates used all his interest in favour of Gordius; but the latter being excluded by the Romans, one named Ariobarzanes was chosen by a majority of votes.

Ariobarzanes.

To enforce this election, Sylla was sent into Cappadocia. He had the character of ambassador, but the real intention of his embassy was to disappoint the ambitious designs of Mithridates. With a handful of forces he defeated a numerous army of Cappadocians and Armenians commanded by Gordius, and settled Ariobarzanes on the throne. But no sooner was Sylla gone than Mithridates stirred up Tigranes king of Armenia against Ariobarzanes, who, without making any resistance, fled to Rome, and Tigranes restored the kingdom to Ariarathes the son of Mithridates. At the same time died the king of Bithynia; and upon his death Mithridates immediately invaded that country, and drove out Nicomedes, the natural son of the deceased king. But the expelled prince fled to Rome, and being assisted by that powerful republic, the king of Pontus was soon obliged to abandon Bithynia and Cappadocia.

War of Mithridates with the Romans.

The Romans having now become exceedingly jealous of the power and ambition of Mithridates, resolved to humble him at any sacrifice. For this purpose they sent ambassadors to the kings of Bithynia and Cappadocia, desiring them to make inroads into the territories of Mithridates, and treat them as they pleased, at the same time assuring them of powerful assistance in case they should have occasion. Ariobarzanes could not by any means be induced to provoke so powerful a neighbour; but Nicomedes being induced to comply, partly by promises and partly by menaces, entered Pontus, where he laid waste whole provinces with fire and sword. Mithridates complained to the Roman legates; but they replied that he had himself been the aggressor, that Nicomedes had only paid him in his own coin, and that they would not allow him to hurt their friend and ally. Upon this Mithridates, having entered Cappadocia with a numerous army, put to flight the united forces of Ariobarzanes and Altinius the Roman legate, thus making himself once more master of that kingdom. In the mean time he sent ambassadors to Rome, complaining of the proceedings of Nicomedes. But his ambassadors met with a very indifferent reception, being enjoined to tell their master that he must either restore the kingdom of Cappadocia to Ariobarzanes, and make peace with Nicomedes, or be accounted an enemy of the Roman people. With this answer they were commanded to depart the city that very day, and told that no more ambassadors could be admitted till their commands were obeyed.

In the mean time both parties prepared for war. The Roman legates in Asia drew together all the forces they could muster in Bithynia; Cappadocia, Paphlagonia, and Galatia; and, being joined by Cassius, governor of Asia, took the field against Mithridates in the year 89 before Christ. They divided their army into several small bodies. Cassius encamped on the confines of Bithynia and Galatia; Manius Aquilius with his division possessed himself of the avenues leading from Pontus into Bithynia; Quintus Oppius secured the entrance into Cappadocia; and the admirals Minucius Rufus and C. Popilius lay with a fleet of three hundred sail at Byzantium, to prevent the enemy from entering the Euxine Sea. Each of the generals had under his command an army of forty thousand men, besides a body of fifty thousand foot and six thousand horse brought to their assistance by Nicomedes.

On the other hand, Mithridates having invited several of the neighbouring nations to join him, collected an army of two hundred and fifty thousand foot, fifty thousand horse, and a hundred and thirty chariots armed with scythes, besides three hundred ships and a hundred galleys. Part of this force he detached against Nicomedes, and utterly defeated him, though much superior in number, whilst obeying the order of Cassius in taking possession of an advantageous post. Another part he detached against Manius Aquilius, whom he also defeated with the loss of ten thousand killed on the spot, and three thousand taken prisoners. On this the other Roman generals abandoned their posts, the fleet also dispersed, and most of the ships were either taken or sunk by the admirals of Mithridates.

The king of Pontus having now resolved to improve the opportunity for driving the Romans entirely out of Asia, overran all Phrygia, Mysia, Asia Proper, Caria, Lycia, Pamphylia, Paphlagonia, and Bithynia, with the rest of the countries which had either belonged to or sided with the Romans, as far as Ionia. He was everywhere received with the greatest demonstrations of joy; the inhabitants flocking to him in white garments, and calling him their father, deliverer, and sole lord of all Asia. What gained him the affections of the people was his kind usage of the prisoners he had taken in the two engagements above mentioned, whom he not only sent home without ransom, but furnished with provisions and money sufficient to defray their expenses by the way. Ambassadors flocked to him from all parts, and amongst these some came from Laodicea on the Lycus, to which the king had promised his protection, provided the people delivered up to him Q. Oppius, governor of Pamphylia, who had fled thither for protection. This request was readily complied with; and Oppius was sent to him in chains, with lictors walking before him in derision of the Roman pride and ostentation. Mithridates was overjoyed to see a Roman general and proconsul in his power; and his joy was soon afterwards increased by the arrival of Manius Aquilius, whom the Lesbians, having revolted against the Romans, sent to him in fetters, together with many other Romans of distinction who had taken shelter amongst them. As Aquilius had been the chief author of the war, Mithridates led him about with him wherever he went, either bound on an ass, or on foot coupled with Bastarnes, a public malefactor, compelling him to proclaim to the crowds who came to see him, that he was Manius Aquilius the Roman legate. When he arrived at Pergamus, he caused Aquilius to be first publicly whipped, then to be put on the rack, and lastly he ordered molten gold to be poured down his throat.

Cruel massacre of the Romans in Asia.

Mithridates being now looked upon as invincible, all the free cities of Asia received him as their sovereign, contributing large sums towards defraying the expenses of the war, by which means he became possessed of treasures which enabled him to keep for years several armies in the field, without levying any taxes upon his subjects. As many Roman citizens were dispersed in the provinces which Mithridates had subdued, he considered these as so many spies, who would not fail to send an account of his proceedings to Rome. For this reason he resolved to cut them off at once by a general massacre; a barbarous policy, which, it is said, had never been heard of till his time, but has since been practised by other nations. He despatched private letters to all the governors and magistrates of the cities where the Romans resided, enjoining them, on pain of death, and the entire destruction of their country, to cause the whole Italian race, women and children not excepted, to be murdered on the thirtieth day from the date of his letters, and to let their bodies remain unburied in the open fields. One moiety of their goods was to be forfeited to the king, and the other bestowed as a reward on the assassins. Whatever slave murdered his master was to receive his liberty, and one half of the debt was to be remitted to the debtor who should kill his creditor. Whoever concealed an Italian, under any pretence whatever, was to be punished with immediate death. On the fatal day, all the gates of the cities being shut, and the avenues guarded by soldiers, the king's orders were proclaimed; which caused an universal horror, not only amongst the unhappy victims themselves, but amongst those who had any feelings of humanity, at seeing themselves obliged either to betray and murder their innocent guests, friends, and relations, or to become liable to a cruel death. However, as most of the Asiatics bore a mortal hatred of the Romans, and were besides animated by the promise of an ample reward, the orders were without delay put into execution. The inhabitants of Ephesus, where Mithridates then resided, dragged such as had taken sanctuary in the temple of Diana from the very statue of the goddess, and put them to the sword. The Pergamenians discharged showers of darts upon them as they embraced the statues in the temple of Æsculapius. At Adramyttium, in Mysia, many were murdered in the water, whilst they were attempting to swim across to the island of Lesbos with their children on their backs. The Caunians, who not long before had been delivered from the yoke of the Rhodians, and restored to their ancient privileges, excelled all others in cruelty. As if they had apostatized from human nature, they took pleasure in tormenting and butchering the innocent children before their mothers' eyes; some of them running distracted, and others dying with grief at a sight which nature could not endure. The Trallians were the only people on the continent who had not the cruelty to imbrue their hands in the blood of the innocent Italians. However, as the king's orders were peremptory, they hired one Theophilus, a Paphlagonian, to despatch the few Romans who lived amongst them; and he, having shut them all up together in the temple of Concord, first cut off their hands as they embraced the statues of the gods, and then hacked them in pieces. Many Romans were saved on the floating islands of Lydia, called *Calaminæ,* where they concealed themselves till such time as they found an opportunity of escaping out of Asia. According to Plutarch and Dion, a hundred and fifty thousand Roman citizens were nevertheless massacred upon that day; but, according to others, only eighty thousand.

Reduction of the island of Cos.

Mithridates having now got rid of those whom he was in dread of on the continent, embarked great part of his forces in order to reduce the islands of the Archipelago. At Cos he was gladly received, and had delivered up to him the young Alexander, son of Alexander king of Egypt, who being driven out of that country, was killed by Charcas, a sea-captain, as he was retiring in a small vessel to Cyprus. With the young prince, they put into the king's hands vast sums of money, besides all the golden vessels and jewels, to an immense value, which his grandmother Cleopatra had for years been amassing. To the young prince Mithridates gave an education suitable for a king's son, but kept the treasures to himself. Here likewise he found eight hundred talents in ready money, which, at the first breaking out of the war, had been deposited by the Jews of Asia, and were designed for the temple of Jerusalem.

Failure of his attempt upon Rhodes.

From Cos Mithridates steered his course for Rhodes, where at that time all the Romans who had escaped the massacre above mentioned found a sanctuary, and, amongst others, L. Cassius the proconsul. The Rhodians, however, being very expert in maritime affairs, Mithridates did not think proper to venture an engagement. As the enemy's fleet advanced, therefore, he retired; but six of the Rhodian ships coming up with twenty-five of his, a sharp action ensued, in which the Rhodians sunk two of the king's ships, and put the rest to flight. In this encounter, though Mithridates had never seen a sea-fight before, he behaved with great intrepidity; but one of the ships of his own squadron falling foul of that which carried him, he was very near being taken prisoner. From this time he abhorred the sea, and took an aversion to the Chians, because the pilot of the ship was a Chian. However, he again appeared before the island; but was forced anew to leave it with disgrace, and to abandon all thoughts of reducing it.

Greece reduced by his generals.

Mithridates now retired into Asia with a design to settle the civil government of the countries which he had conquered, committing the care of the war to his generals. Archelaus, his generalissimo, was sent into Greece with an army of a hundred and twenty thousand men; where, by treachery, he made himself master of Athens, and either put to the sword or sent to Mithridates all those who favoured or were suspected of favouring the Romans. From Athens he despatched parties to reduce the neighbouring castles and the island of Delos, which they accordingly effected; but Orobius, a Roman general, hearing that the enemy kept no guards, and passed their time in carousing and debauchery, fell upon them unexpectedly, and cut off the whole party, except Apellicon the commander.

In the mean time Metrophanes, another of the king's generals, entering Eubœa, laid waste the whole country, directing his rage chiefly against the cities of Demetrias and Magnesia, which refused to open their gates to him. But as he was sailing off with a great booty, Bryttius, the prætor or governor of Macedonia, having come up with him, sunk some of his ships, and took others, putting all the prisoners to the sword. Upon the news of this loss, Mithridates sent his son Ariarathes with a powerful army to invade Macedonia, which he soon reduced, together with the kingdom of Thrace, driving the Romans everywhere before him. The generals whom he sent into other quarters were not less successful; so that Mithridates had, according to Aulus Gellius, twenty-five different nations who paid him homage. The same author adds, that he was skilled in every one of their various languages, and could converse with the natives without an interpreter. Amongst these nations we find the Rhoxani, now the Russians or Muscovites, whom Diophantes, one of the king's generals, brought under subjection, after having slain in an engagement some fifty thousand of the barbarians.

Sylla sent against Mithridates.

During all this time the Romans had been too much occupied with their own domestic quarrels to take such effectual measures as they otherwise would have done for checking the progress of Mithridates. But at last, having received certain advice that the king designed to invade Italy, and that he had even been solicited to do so by some of the revolted Italians, they sent against him Lucius Sylla, who had already given sufficient proofs of his courage, conduct, and experience in war. Sylla had with him only five legions and a few cohorts. But with this inconsiderable force he landed in Attica, and in a short time made himself master of the capital; Archelaus not daring, or, according to others, not caring, to engage him. As Sylla had but a few frigates, he sent Lucullus to the island of Rhodes, with orders to the Rhodians to join him with their fleet. The undertaking was very dangerous, as the king's fleet in a manner covered the sea. However, Lucullus, despising all danger, ventured out, and sailed, without meeting with any accident, to Syria, Egypt, Libya, and Cyprus; whence he returned with such supplies of ships and experienced mariners, as enabled Sylla, after their junction with the Rhodians, to act offensively by sea as well as by land. Archelaus now despatched messengers to Taxiles, who commanded in Thrace and Macedonia, desiring him to join with all his forces; and

Taxiles having obeyed, they mustered an army of a hundred and twenty thousand men. Sylla met them near Cheronæa with only fifteen thousand foot and fifteen hundred horse; but gave them a dreadful overthrow, no fewer than a hundred and ten thousand of the Asiatics having fallen in battle, whilst the Romans lost only a few men.

Victories of Sylla.

This success having excited envy and jealousy against Sylla in Rome, the senate sent Lucius Valerius Flaccus, the consul of that year, with two legions, into Asia; apparently to attack Mithridates on that side, but in reality with private instructions to fall upon Sylla himself, if they found him disaffected to the senate. But as Flaccus was a man of no experience in war, C. Fimbria, a senator of great repute amongst the soldiery, was appointed to attend him in the character of legate and lieutenant-general. Sylla was at that time in Bœotia; but, hearing what had occurred at Rome, he marched with all expedition into Thessaly, designing to encounter Flaccus, who, he expected, was to land in that province. But no sooner had he left Bœotia, than the country was overrun by an army of Asiatics, under command of Dorylaus, the chief favourite of the king. On learning this, Sylla returned into Bœotia, where he gained two signal victories, which put an end to the war in Greece. In the first of these Dorylaus lost a hundred and fifty thousand men according to some authors, or two hundred thousand according to others; and in the next all the remainder. In this last engagement twenty thousand were driven into a river, where they perished to a man; an equal number were pursued into a marsh, and entirely cut off; and the remainder were killed in the heat of the battle, the Romans giving no quarter to men who had treated their fellow-citizens in such a cruel and barbarous manner in Asia. Plutarch tells us, that the marshes were dyed with blood; that the course of the river was stopped by the dead bodies; and that even in his time, that is, near two hundred years afterwards, a great number of bows, helmets, coats of mail, and swords, were found buried in the mud. Archelaus, who had joined Dorylaus with a body of ten thousand men a few days before the battle, lay three days stripped amongst the slain, until he found a small vessel which carried him to Eubœa, where he collected what forces he could, but was never again able to take the field. Indeed Livy tells us, that Archelaus betrayed the king's cause; and Aurelius Victor says that the king's fleet was intercepted by Sylla through the treachery of Archelaus. That there was a good understanding between the two commanders, says the latter, was plain from Sylla's bestowing upon Archelaus ten thousand acres of land near the city of Chalcis in Eubœa. Strabo also informs us, that Archelaus was afterwards greatly esteemed and caressed by Sylla and the senate; but Sylla himself in his Commentaries, and Dio Cassius, endeavour to clear Archelaus from all suspicion of treachery.

Flaccus put to death by Fimbria.

In the mean time, Sylla having given up Bœotia to be plundered by his soldiers, marched into Thessaly, where he took up his winter-quarters, and caused his old ships to be refitted and several new ones built, in order to pass over into Asia in the beginning of the spring, that he might drive from thence not only Mithridates, but also his rival Flaccus, whom the senate, out of opposition to him, had appointed governor of that province. But before he arrived, some differences having arisen between Flaccus and Fimbria, the latter was deprived of his command by the consul. Upon this Fimbria, having gained over the soldiery, made war upon the consul, took him prisoner, put him to death, and assumed the command of all the Roman forces in Asia. In this situation he behaved with the greatest cruelty, insomuch that his name became more odious than even that of Mithridates himself. This hatred the king of Pontus endeavoured to improve to his own advantage; and therefore he commanded his son, also called Mithridates, to join Taxiles, Diophantes, and Menander, three of his most experienced commanders, and to return at the head of a numerous army into Asia; not doubting that the inhabitants, thus harassed by Fimbria, would shake off the Roman yoke when they saw such a powerful army in the field ready to protect them. But Fimbria, distrusting the Asiatics, marched out to meet the enemy, and offered them battle before they entered the province. As the king's army was greatly superior to the Romans in number, the latter suffered severely in the engagement, but held out until night put an end to the contest, when they withdrew to the opposite side of a river, which was at a small distance from the field of battle. Here they designed to intrench themselves; but a violent storm having in the mean time arisen, Fimbria laid hold of that opportunity to repass the river and surprise the enemy, of whom he made such havock, that only the commanders and some few troops of horse escaped. Amongst these was the king's son, who, attended by a few horsemen, got safe to Pergamus, where his father resided. But Fimbria, pursuing him day and night without intermission, entered Pergamus sword in hand; and, hearing that both Mithridates and his son had fled from thence a few hours before, continued his pursuit, and would have taken the king himself, had he not entered Pitane with a considerable body of horse. The place was closely invested by Fimbria; but as he had not ships to blockade it by sea, he sent a messenger to Lucullus, who commanded the Roman navy in Asia, entreating him, as he tendered the welfare of the republic, to make what haste he could to Pitane, and assist him in taking the most inveterate enemy of Rome. But Lucullus, preferring the gratification of a private pique to the good of his country, refused to put to sea; and thus allowed the fleet of Mithridates to carry him in safety to Mitylene.

Peace concluded.

Soon after the king's departure, Fimbria took Pitane by storm, and reduced most of the cities of Asia, particularly Troy, which he also took by assault, putting most of the inhabitants to the sword, because they had sent an embassy to Sylla, offering to submit to him rather than to Fimbria. To add to the misfortunes of Mithridates, his fleet was entirely defeated in two engagements by Lucullus; so that he began to be weary of the war, and therefore desired Archelaus to conclude a peace, upon as honourable terms as he could. The king himself also had afterwards a conference with Sylla, and a peace was concluded in the year 85 before Christ. The terms were, that Mithridates should relinquish all his conquests, and content himself with his paternal dominions, which were confined within the limits of Pontus; that he should immediately resign Bithynia to Nicomedes, and Cappadocia to Ariobarzanes, and release without ransom all the prisoners he had taken during the war; that he should pay to the Romans two thousand, or, as others will have it, three thousand talents, and deliver up to Sylla eighty ships with all their arms and ammunition, besides five hundred archers; and, lastly, that he should not molest such cities or persons as had during the war revolted from him and sided with the Romans.

Sylla, having thus concluded the war with great glory to himself and equal advantage to the republic, turned his army against Fimbria; but the latter, finding himself in no condition to oppose his rival by force, had recourse to treachery, and attempted to get Sylla assassinated. The plot miscarried, however, and Fimbria put an end to his own life. Sylla, having now an uncontrolled power in Asia, declared the Chians, Rhodians, Lycians, Magnesians, and Trojans, free, and friends of the people of Rome, by way of reward for their having sided with the Romans; but on the other cities he imposed heavy fines, condemning them in one year to pay twenty thousand talents, and quartering his soldiers in the houses of those who had shown disaffection to the Romans. Each private man was to receive from his landlord sixteen drachms a day, and each officer fifty; and, besides, both were to be supplied with provisions, not only for themselves, but also for such of their friends as they thought proper to invite. By these impositions most of the people of Asia were reduced to beggary; especially the inhabitants of Ephesus, who, above all others, had shown hatred against the Romans. Having collected immense treasure, Sylla then set sail for Italy; leaving behind him Lucullus in the character of quæstor, and Muræna in that of prætor. The two legions which Fimbria had commanded were given to Muræna, because Sylla suspected them of an inclination to the faction of Marius, whose party he was going to crush at Rome.

The na-ions that ad revolt-d against Mithrida-es crushed y him.

In the mean time Mithridates had no sooner returned into Pontus, than he set about the reduction of those nations which had revolted against him during the war. He began with the Colchians, who immediately submitted, upon condition that Mithridates would give them his son for king. This was complied with; but the old king had thenceforward a jealousy of his son, whom, accordingly, he first imprisoned and then put to death. Soon after this, the king having made great preparations under pretence of reducing the Bosphori, a warlike nation who had revolted against him, the Romans began to be jealous; and their suspicion was further increased by Archelaus, who, having fled to them, assured them that the preparations of Mithridates were not at all designed against the Bosphori. On hearing this, Muræna invaded Pontus without any further provocation. The king reminded him of the articles of peace concluded with Sylla; but Muræna replied that he knew of no such articles; for Sylla had set down nothing in writing, but contented himself with the execution of what had been agreed upon. Having given this answer, the Roman general began to lay waste and plunder the country, without sparing even the treasures or temples consecrated to the gods. Having put all to fire and sword on the frontiers of Pontus towards Cappadocia, he passed the river Halys, and on that side possessed himself, without opposition, of four hundred villages; for Mithridates was unwilling to commit any hostilities before the return of an ambassador whom he had sent to Rome to complain of the conduct of Muræna. At length the ambassador returned, and along with him one Callidius, who, in a public assembly, commanded Muræna to forbear molesting a friend and ally of the Roman people; but afterwards, calling him aside, he had a private conference with him, in which it is supposed, as he brought no decree of the senate, that he encouraged him to pursue the war. Whatever there might be in this, however, it is certain that Muræna still continued to practise the same hostilities, and even made an attempt on Sinope, where the king resided and the royal treasures were deposited. But as the town was well fortified, he was forced to retire with some loss. In the mean time, Mithridates himself taking the field, appeared at the head of a powerful army, drove the Romans out of their camp, and forced them with great slaughter to save themselves by flying across the mountains into Phrygia. This sudden victory again induced many cities to join Mithridates, and gave him an opportunity of once more driving the Romans out of Cappadocia.

lithridates ngages in a ew war ith the omans.

In the mean time, Sylla, having been created dictator at Rome, sent a messenger to Muræna, charging him in his name not to molest Mithridates, whom he had honoured with the title of a friend and ally of Rome. Muræna did not think proper to disregard this message; and therefore immediately abandoned all the places he had seized, whilst Mithridates again renounced Cappadocia, giving his own son as an hostage of his fidelity. Being then at leisure to pursue his other plans, Mithridates fell upon the Bosphori; and, having soon subdued them, appointed Machares, one of his sons, king of the country. But leading his army from thence against the Achæans, a people bordering on the Colchians, and originally descended from the Greeks, who, returning from Troy, had mistaken their way into Greece, and settled there, he was defeated with the loss of three fourths of his men. On his return to Pontus, however, he recruited his army, and made vast preparations to invade them anew; but, in the mean time, hearing of Sylla's death, he came to the imprudent resolution of entering into a second war with the Romans. Having therefore induced his son-in-law, Tigranes, king of Armenia, to invade Cappadocia, he himself entered Paphlagonia at the head of a hundred and twenty thousand infantry disciplined after the Roman manner, sixteen thousand horse, and a hundred chariots armed with scythes. This country readily submitted, after which the king marched into Bithynia, which also submitted without opposition; and the province of Asia followed the example, for these countries, being oppressed with exorbitant taxes, looked upon him as their deliverer. In entering the cities of Asia, he caused M. Marius or Varius, whom Sertorius had sent him from Spain to discipline his troops, walk before him with the ensigns of consular dignity, as if he was the chief magistrate; the king following as one of his attendants. He made several cities free, but at the same time acquainted the inhabitants that they were indebted to Sertorius for their liberty; and thus, by the connivance of that general, many cities revolted from the Romans without knowing that they had done so. But in the mean time, Julius Cæsar, being at that time at Rhodes, whither he had gone to study oratory, and hearing what havock the king's officers had made in the adjacent countries, collected what troops he could, and falling unexpectedly upon them, expelled them from the province of Asia.

Lucullus and Cotta sent against him.

The Roman senate, now finding a war unavoidable, appointed Lucullus to conduct it. The other consul, Cotta, having solicited an employment in this war, was sent with a fleet to guard the Propontis and defend Bithynia. Lucullus having raised one legion in Italy, passed over with it into Asia, where he was joined by four others, two of which, as they had served under Fimbria, proved at first very mutinous and refractory; nor were the others much better disposed, having been immersed in, and demoralised by, Asiatic luxuries. The disciplining of these troops consumed a considerable time, which proved prejudicial to the Roman affairs; for almost all the Asiatics were ready to revolt, and Mithridates was making the greatest preparations. One of his armies was ordered to march into Cappadocia, under the command of Diophantes Matharus, in order to oppose Lucullus if he should attempt to enter Pontus on that side; another, commanded by Mithridates in person, consisted of one hundred and fifty thousand infantry, twelve thousand horse, and a hundred chariots armed with scythes; a third army, commanded by Marius and Eumachus, two generals of great experience in war, was encamped in the neighbourhood of Heraclea in Pontus.

Mithridates at first successful.

The beginning of the war proved favourable to Mithridates. Cotta, being desired by Lucullus to keep his fleet within the harbour, as being inferior to that of Mithridates, resolved to take the first opportunity of fighting the king by land, not doubting of an easy victory. Having for this purpose collected all the forces he could, Cotta despatched his lieutenant, P. Rutilius, with a considerable body, to observe the motions of the enemy. This commander being met by Marius and Eumachus, an engagement ensued, in which the Romans were defeated, and the greater part of them, with their commander, cut in pieces. The same misfortune befell several other officers of distinction sent to oppose Mithridates, who, elated with success, ordered his admiral to sail into the very harbour, and set fire to the Roman fleet. This was accordingly performed without the least opposition from Cotta; and sixty ships were taken, sunk, or burned, on that occasion.

His reverses.

These victories, having increased the rebellious disposition of the Asiatics, induced Lucullus to hasten his march, in order to stop the progress of the enemy. But finding the king's army much more numerous that he expected, he thought proper to decline an engagement. However, several skirmishes happened, in which the Romans had always so much the advantage, that they became impatient for a general engagement. But Lucullus did not at this time choose to run so great a risk; and therefore Mithridates, seeing that he could not force the Romans to a battle, decamped in the night-time, and by day-break reached Cyzicum, an important city, warmly attached to the Romans. Lucullus pursued him; and, falling on his rear, killed ten thousand, and took thirteen thousand prisoners. After this, the Roman general, by a manœuvre, gained an important pass, which enabled him to cut off all communication between the army of Mithridates and the neighbouring country. The king, seeing himself thus in danger of famine, redoubled his efforts to gain the city; but finding that he could not batter down the walls, he resolved to undermine them. In this also he was unsuccessful; the besieged sunk countermines, and had very nearly taken the king himself in one of his own mines. In the mean time, winter coming on, the army of Mithridates was so distressed for want of provisions, that many died of hunger, whilst the survivors were forced to feed on the flesh of their dead companions. The famine was followed by a plague, which destroyed such numbers that Mithridates was obliged to think of a retreat; and even this had become very dangerous. However, he laid hold of the opportunity when Lucullus proceeded to besiege a neighbouring castle, and sent off the greater part of his cavalry in the night, ordering them not to halt till they were out of the reach of the enemy. But Lucullus having got intelligence of their march, suddenly returned, and pursued them so closely that he came up with them as they were passing a river, took six hundred horse, all their beasts of burden, fifteen thousand men, and put the rest to the sword. On his return he fell in with Aristonicus, the king's admiral, whom he took, just as that commander was ready to sail with a large sum of money designed to bribe the Roman army. In the mean time, Mithridates, finding himself reduced to the last extremity, embarked in the night-time with the greater part of the forces, whilst Marius and Eumachus, with thirty thousand men, made the best of their way to Lampsacus. But being closely pursued by the Romans, they were overtaken at the river Æsopus, which at that time was not fordable, from having been swelled by heavy rains. Twenty thousand were killed on the spot; nor would a single man have escaped, had not the Asiatics scattered great quantities of gold and silver in the way, that the march of the Romans might be retarded by their stopping to gather it up. Lucullus on his return entered Cyzicum amidst the acclamations of the citizens, who afterwards instituted public sports in honour of him, which they called *Lucullea*. The city was declared free, and all the privileges, exemptions, and immunities, which were enjoyed by the inhabitants of Rome itself, were bestowed upon the citizens.

Great victory gained by Lucullus.

From Cyzicum, Lucullus marched along the coast of the Hellespont until he came to Troas, where he equipped his fleet, and put to sea in quest of Marius, Alexander, and Dionysius, three of the king's generals, who had a fleet of fifty ships, with ten thousand soldiers on board. Lucullus came up with them near the island of Lemnos, took thirty-two of their ships, and put a great number of their troops to the sword. The day after the engagement the three generals were discovered in a cave, where they had concealed themselves, and dragged from thence to Lucullus, who, after having severely upbraided Marius for fighting against his country, caused him to be put to death. Alexander and Dionysius were reserved for the triumph; but the latter poisoned himself to avoid that disgrace. Lucullus then steered his course for Bithynia, on receiving intelligence that Mithridates had appeared with his fleet upon those coasts. But the king having received notice of his approach, made what haste he could to gain Pontus, and arrived at Heraclea on board a pirate named Selemus, with whom he was obliged to trust himself, his fleet being dispersed by a violent storm, and the ship that carried him cast away.

Further successes of Lucullus.

In the meanwhile Mithridates was no less unfortunate by land than by sea. Triarius, one of the officers of Lucullus, reduced the cities of Apamea, Prusa, Prusias, and Nicæa, and marched thence with all expedition to Nicomedia, where the king himself was, and near which place Cotta lay encamped. But before the two armies could effect a junction, Mithridates escaped, first to Heraclea, which was betrayed to him, and then to Sinope. Nor did Lucullus himself remain all this time inactive. Having reduced all Paphlagonia and Bithynia, he marched into Cappadocia, and joined Cotta and Triarius at Nicomedia, with a design to invade Pontus; but hearing that Heraclea was in the hands of Mithridates, he despatched Cotta to reduce that city. Triarius was ordered to proceed with the fleet to the Hellespont and Propontis, to intercept the king's fleet, which was daily expected from Spain with supplies from Sertorius. Lucullus himself, with the main strength of the army, pursued his march into Pontus. His army was greatly harassed, especially in the narrow passes between Cappadocia and Pontus, by flying parties of the enemy. But the greatest inconvenience was the want of provisions, as the king's troops had laid waste all the country around; insomuch that Lucullus, having lost almost all his beasts of burden, was obliged to take along with the army thirty thousand Galatians, each of them carrying a sack of corn on his back. At last, however, he gained the plains of Pontus, where provisions were so plentiful that an ox was sold for a drachma, and everything else in proportion.

The Roman general having now carried the war into the enemy's country, divided his forces, and at the same time invested a very strong town named Amisus; another called Eupatoria, built by Mithridates, and made the place of his residence; and a third named Themiscyra, situated on the banks of the Thermodon. Eupatoria was soon taken, but Themiscyra made a vigorous resistance, and the townsmen galled the Romans to such a degree, that, not daring to approach the walls openly, they contented themselves with undermining them. But in this, too, they met with no small difficulty, for the enemy countermined, and often engaged them under ground, letting into the mines bears and other wild beasts, with swarms of bees, which obliged them to abandon their works. However, the town was at last obliged to surrender for want of provisions. As for Amisus, Lucullus himself sat down before it. But finding it strongly fortified, and garrisoned with the flower of the king's troops, the Roman general thought proper to reduce it by famine; and on this occasion his countrymen first complained of him as protracting the war for his own advantage.

Mutiny in the army of Mithridates, and flight of the king.

In the mean time, Mithridates having recruited his shattered army, advanced to Cabiræ, a city not far distant from Amisus; and Lucullus, leaving part of the army to continue the siege, marched at the head of the rest to oppose Mithridates. But the king having drawn his cavalry into a general engagement, defeated them with considerable loss, and drove them back to the mountains, through the passes of which Lucullus had lately marched to attack him. This check obliged the Roman general to retire to a rising ground near to the city of Cabiræ, where the enemy could not force him to an engagement. Here provisions beginning to grow scarce, Lucullus sent out strong parties from his army into Cappadocia, the only place whence he could receive supplies. One of these parties entirely defeated Taxiles and Diophantes, two of the king's generals, who had been stationed there to prevent Lucullus from having any communication with the country. The king, on receiving the news of this defeat, resolved to break up his camp and to retire, not doubting that Lucullus would attack him as soon as his forces returned. This resolution he no sooner imparted to his nobles, than they began privately to send away their most valuable property; and when it was discovered by the soldiers, they were so much displeased that they plundered their baggage, and put those who had the care of it to the sword. After this they betook themselves to flight, crowding out of the gates in the utmost confusion. The king hastened to stop their flight; but nobody showing him the least respect, he was carried away by the crowd, and in great danger of being trampled to death. Having with difficulty made his escape, he retired with a small retinue, first to Cabiræ, and then to his son-in-law Tigranes, king of Armenia. Lucullus despatched the best part of his cavalry in pursuit of the fugitives, whilst he himself, with the rest, invested the camp of Mithridates, where those only remained who could not fly with the rest. The camp was easily taken; but most of the soldiers made their escape, whilst the Romans, contrary to their general's orders, were busied in plundering. Lucullus then closely pursued the king, who, being overtaken by a company of Galatians, caused a mule loaded with part of his treasures to be driven in amongst them, by which means he made his escape, whilst they quarrelled about the booty. Mithridates, remembering in his flight that he had left his sisters, wives, and concubines at Pharnacia, despatched an eunuch named Bacchus or Bacchides with orders to put them all to death, lest they should fall into the hands of the enemy; and this cruel order was accordingly obeyed.

ns under
cullus.

After the flight of Mithridates, the Romans no longer met with any opposition; the king's governors flocking from all parts to place themselves under the protection of the conqueror. Amongst these were the grandfather of Strabo the geographer, whom the king had disobliged by putting to death his cousin-german Tibias, and his son Theophilus. He was a man of such credit, that no sooner had he abandoned the king's party, than fifteen other commanders delivered up to Lucullus the places with which they had been intrusted; and about the same time Triarius, falling in with the king's fleet near the island of Tenedos, obtained a complete victory, having either taken or sunk sixty of the enemy's ships.

During all this time Cotta had been employed without success in besieging Heraclea, which he could never have reduced without the assistance of Triarius. That commander, having defeated the fleet, reduced the town to such distress, that a third part of the garrison died of hunger; upon which the governor, Conacorix, privately agreed with Triarius to deliver up one of the gates to him. This was accordingly done; and the Romans entering, made a terrible slaughter of the helpless inhabitants. But in the mean time Cotta, provoked at seeing himself deprived both of all share of the booty and the honour of reducing a place which he had so long besieged, fell upon his countrymen as they were busied in plundering; a proceeding which would have occasioned a great deal of bloodshed, had not Triarius promised to divide the booty equally. Conacorix, to conceal his treachery, after marching out of Heraclea, seized on two forts belonging to the Romans; and Triarius being sent to recover them, Cotta, in his absence, plundered the city anew, rifled the temples which the other had spared, put all the citizens he could meet with to the sword, and having carried off everything valuable, at last set fire to the city in several places, by which means it was soon reduced to ashes. Cotta then, having no further occasion for his troops, dismissed the auxiliaries, resigned his legions to Lucullus, and put to sea himself in order to return to Rome. But he had scarcely got out of the harbour, when part of his ships, being overloaded with the spoils of the city, sunk; and the others, driven by a violent north wind, were dashed against the shore, which occasioned the loss of a great part of the booty. Upon his return to Rome, however, he was highly applauded by the senate, and honoured with the title of *Ponticus*.

Lucullus, having now reduced Pontus, marched against the Chaldæans, Tibarenians, and inhabitants of Armenia Minor, who voluntarily submitted to him, and put him in possession of all their strongholds. From Armenia he returned to Amisus, which still held out; Callimachus, governor of the place, having harassed the Romans to such a degree, by engines of his own contrivance, that they had given over their assaults, and contented themselves with blocking it up by land, though the garrison was at the same time plentifully supplied with provisions by sea. Lucullus, on his arrival, summoned the city to surrender, offering the inhabitants honourable terms; but these being refused, he made a general assault at the time when he knew that Callimachus used to draw off the greater part of his troops to give them some respite. The Romans applying their scaling ladders, got over the wall before Callimachus could come to the assistance of those whom he had left to guard it; however, by setting the city on fire, he found means in the confusion to make his escape. Lucullus commanded his men to use their utmost endeavours to save the city; but being intent only upon plundering, they regarded nothing except the furniture. At last the fire was extinguished by a violent shower; and Lucullus, having with difficulty restrained his soldiers from committing any further excesses, in some measure repaired the city before he left it, and suffered the inhabitants to enjoy their possessions in peace.

Nothing was now wanting but the captivity of Mithridates himself to put a final period to the war; and therefore Lucullus demanded him from his son-in-law Tigranes. But though that prince could not be prevailed on to see Mithridates on account of his misconduct, he could as little be induced to deliver him up to his enemies. After this refusal, however, he for the first time condescended to see his father-in-law, who had already resided for about a year and eight months in his dominions. In a private conference held by the two kings, it was agreed that Tigranes should march against the Romans, and Mithridates, with ten thousand cavalry, return into Pontus, where he should make what levies he could, and rejoin Tigranes, before Lucullus, who was then employed in the siege of Sinope, could enter Armenia. But Sinope having, in the mean time, surrendered, Lucullus marched with all possible expedition against Tigranes, and having drawn him into a general engagement, entirely defeated him.

Defeats of Tigranes and Mithridates.

Mithridates was marching to his assistance, when he met his son-in-law flying with a small retinue to shelter himself in some remote corner of the kingdom. He encouraged him to raise new forces, not doubting but that another campaign would repair all former losses, provided he would commit to his management everything relating to the war. To this Tigranes acceded, and as he thought his father-in-law more qualified to deal with the Romans than himself, orders were issued for raising a new army, whilst all the Armenians able to bear arms were summoned to meet at the place of the general rendezvous. Out of these Mithridates chose seventy thousand foot and thirty-five thousand horse; and having trained them during the winter, after the Roman discipline, in the beginning of the spring he left part of them with Tigranes, and marched himself with the rest into Pontus, where he recovered many important places, and overcame in a pitched battle M. Fabius, whom Lucullus had appointed governor of that province. Flushed with his success, as soon as the wounds he had received in the engagement suffered him to move, he pursued Fabius, and beseiged him in the city of Cabiræ, whither he had retired; but in the mean time Triarius, who was marching from Asia to join Lucullus, hearing of the distress of the Romans, hastened to their relief, and appearing unexpectedly on the neighbouring hill, struck such terror into the enemy, that they raised the siege, and made the best of their way into Cappadocia. Triarius pursued them, and got so near that the two armies were separated only by a river. Here he halted, with a design to pass the river after he had allowed his men some rest, for they were tired out with long marches. But Mithridates was beforehand with him, and crossing the river on a bridge, where he had placed a strong guard, attacked the Romans with great resolution before they had time to refresh themselves. The battle was bloody, and the event doubtful, till the bridge breaking down with the weight of the multitude that passed, the king's troops who had engaged, relying chiefly upon their numbers, began to lose courage, seeing they could receive no further assistance; and the Romans charging them with fresh vigour, they betook themselves to flight. After this engagement, as winter came on, both armies were glad to retire into winter quarters.

Defeat of Triarius.

During the winter, Mithridates raised new forces; and having received considerable supplies from Tigranes, took the field early in the spring, in hopes of driving the Romans quite out of Pontus, before Lucullus, who had work enough upon his hands in Armenia, could come to their assistance. With this view he marched straight against Triarius and Sornatius, to whom Lucullus had committed the care and defence of that province; and finding them encamped near the city of Gaziursa, he proffered them battle, which they declined. He then set a strong detachment to besiege a castle where the Romans had left all their baggage, hoping they would rather venture an engagement to relieve the place than lose all they had with so much toil and labour obtained during the war. Neither was he disappointed in his hopes; for though Triarius intended to keep close in his camp till the arrival of Lucullus, whom he daily expected, having acquainted him with the danger, the soldiers, hearing that the castle was besieged, declared in a tumultuous manner, that if he did not lead them they would march to the relief of the place without his permission. Triarius being thus forced by his own men to fight, drew out his forces against the king, whose army was three times his number; but whilst they were upon the point of engaging, both armies were forced, by a violent storm, to retire to their respective camps. Triarius having, however, that very day received intelligence of the approach of Lucullus, and fearing he would snatch the victory from his hands, resolved to make a bold push, and next morning by break of day to attack the king in his camp. If he conquered, the glory, he thought, would be entirely his own; if he were overcome, the enemy could reap no great advantage from his victory, Lucullus being at hand with a powerful army. The king was surprised, but putting himself at the head of a few troops of his guards, he sustained the shock of the Romans till the rest of his army came to his relief, and attacked the enemy with such fury, that the Roman infantry were forced to give way, and driven into a morass, where they were surrounded, and great numbers of them cut in pieces.

The cavalry were likewise put to flight, and pursued with great slaughter, till a Roman centurion in the king's service, pitying his countrymen, attempted to kill him. The king's life was saved by his breastplate; but as he received a deep wound in the thigh, he was obliged to discontinue the pursuit himself, and those who were about him caused the retreat to be sounded, which, as it was unexpected, occasioned great confusion in the army. The centurion was immediately cut in pieces; but the Roman horse, getting the start of the enemy, found means to make their escape. Above seven thousand of the Romans were killed in that battle; amongst whom were one hundred and fifty centurions and twenty-four tribunes, the greatest number of officers that had ever before fallen in any engagement. Mithridates being cured of his wound, in order that he might not in future be exposed to such dangers, caused the Romans who served in his army to be formed into one body, as if they were to be sent out on a party; and then ordered them to retire to their tents, where they were all to a man cut in pieces.

The king, however elated with success, yet would not engage Lucullus; but by long marches hastened into Armenia Minor, and encamped on a hill near the town of Talaura, expecting Tigranes, who was advancing with a strong army to join him. Lucullus, in pursuit of Mithridates, marched over the field of battle, leaving those unburied who had fallen in the engagement, which alienated the minds of the soldiery; and they began to be very mutinous, being stirred up by Appius Claudius, whom Lucullus had turned out of his command for his vile behaviour, notwithstanding he was a near connection, Lucullus having married his sister. The discontent that prevailed in the army rose to such a height that Lucullus was obliged to remain in his camp all that summer; the soldiers declaring, in a mutinous manner, that they would not follow him any longer, nor serve under a general who refused to share the booty with them.

Lucullus recalled.

These complaints, and the general discontent which reigned in the army, obliged the senate to recall Lucullus, and appoint Manius Acilius Glabrio, consul of that year, in his room. Glabrio, on arriving in Bithynia, gave notice by public criers to all the cities, that the senate had discharged Lucullus and his army, and confiscated his goods, for protracting the war and refusing to comply with their injunctions. Lucullus was accordingly abandoned by the greater part of his army, and forced to retire into Galatia, not being in a condition to make head against the joint forces of the two kings, who, laying hold of that opportunity, recovered the best part of Pontus, Bithynia, Cappadocia, and Armenia Minor. For although Glabrio had hastened into Pontus, as if he had intended to engage the enemy and rob Lucullus of the victory, yet, upon the first news of the approach of the two kings, he thought fit to retire and leave the country open on all sides to the enemy.

Pompey sent against Mithridates.

When this became known at Rome, a law was enacted there by C. Manilius, a tribune of the people, whereby the management of the war against Mithridates and Tigranes, and likewise the provinces of Cilicia, then under Quintus Marcius, and of Bithynia under Glabrio, were committed to Pompey. By the same law he was continued in that unlimited power by sea, with which he had been invested when he first set out against the pirates of Cilicia. In virtue of this law, Pompey, who had then just ended the war with the Cilician pirates, took upon him the command of the army, and directed the allies of the Roman people to join him with all possible expedition. But before he took the field, he renewed the alliance which Sylla and Lucullus had concluded with Phrahates king of Parthia; and then sent friendly proposals to Mithridates, who at first seemed inclined to give ear to them, and accordingly despatched an ambassador to the Roman army to treat of a peace. Pompey required of him, if he was in earnest, to lay down his arms, and deliver up to him all those who had revolted from the Romans during the war. This demand was no sooner reported abroad in the king's camp, than the deserters, who were very numerous in the king's army, betaking themselves to their arms, threatened to put Mithridates himself to death; and would have occasioned a great disturbance, had not the king appeased the growing tumult, by assuring them that he had sent ambassadors, not to treat of a peace, but only, under pretence of suing for peace, to take a near view of the enemy's strength. He moreover obliged himself, by a solemn oath, in presence of the whole army, never to enter into any treaty of friendship with the Romans, nor to deliver up to them such as had ever served under him.

Pompey finding his proposals rejected, advanced against the king with an army of thirty thousand foot and twenty

lates.

thousand horse, as Plutarch writes, or thirty thousand, all chosen troops, as we read in Appian; for he discharged most of those who had served under Glabrio and Lucullus. As he entered Galatia, he was met by Lucullus, who endeavoured to persuade him to march back, the war being nearly finished, and even deputies sent by the republic to settle the province of Pontus; but not being able to prevail with him, after mutual complaints against each other, they parted; and Pompey removing his camp, commanded the troops that were with Lucullus to join him, except sixteen hundred, whom he left to attend Lucullus in his triumph. Lucullus then set out for Rome, where he was received by the senate with great marks of esteem, most men thinking him highly injured by the authors of the Manilian law. Pompey pursued his march into Pontus; but finding that he could not by any means induce the king to risk a battle, he marched back into Armenia Minor, with a design either to reduce that province, or oblige Mithridates to venture a battle in order to relieve it. Mithridates followed him at some distance, and entering Armenia, encamped over against the Romans, on a hill, where, by intercepting their convoys, he reduced them to such distress that they were obliged to remove to a more convenient place; the king cutting off many in their rear, and harassing them with frequent attacks, till he fell into an ambuscade prepared by Pompey, whose personal courage and prudent conduct on that occasion confirmed the king in his resolution not to hazard a general engagement. The two armies encamped over against each other; Pompey on one hill, and the king on another, near the city of Dastira, in the province of Acisilene, at a small distance from the Euphrates, which divides Cisilene from Armenia Minor.

he king
sieged.

Here Pompey, seeing he could neither draw the king to a battle, nor force his camp, which was pitched on a steep and craggy mountain, began to block him up with a ditch, which he carried round the bottom of the hill where the king was encamped; and meeting with no opposition, he finished his work, thus cutting off the enemy's communication with the country. Pompey was amazed to see the king thus tamely suffer himself to be shut up, and could not help saying, that he was either a great fool or a great coward; a fool, if he did not apprehend the danger; and a coward, if, being apprised of it, he did not to the utmost of his power endeavour to prevent it. By this ditch, which was one hundred and fifty furlongs in circuit, and defended by many forts raised at small distances from each other, the king was so closely besieged, that he could neither send out parties to forage, nor receive the supplies that came to him from Pontus. He was thus besieged for the space of forty-five or fifty days, and his army reduced to such straits, that, having consumed all their provisions, they were at last forced to live on their dead horses. Mithridates therefore resolved at all events to break through the Roman fortifications; and accordingly, having put to the sword all those who were sick or disabled, that they might not fall into the enemy's hands, he attacked in the dead of the night the Roman guards, and having overpowered them with numbers, got safe into the open fields, and continued his march till night towards Armenia Major, where he was expected by Tigranes.

ithridates
ertaken
d defeat-

Pompey next morning by break of day pursued the enemy with his whole army; and having with difficulty overtaken them, found the king encamped on a hill, to which there was but one ascent, and that guarded by a strong body of infantry. The Romans encamped opposite them; but Pompey, fearing the king would make his escape in the night-time, decamped privately, and taking the same route the enemy were to hold in order to gain Armenia, possessed himself of all the eminences and defiles through which the king was to pass. Mithridates, thinking that Pompey had returned to his former camp, pursued his march, and about the dusk of the evening entered a narrow valley, which was surrounded on all sides by steep hills. On these hills the Romans lay concealed, expecting the signal to fall upon the enemy, and attack them upon all sides at once, whilst they were fatigued by their march, and apparently in great security. Pompey was at first for delaying the attack till the next morning, thinking it not safe to engage in the night-time amongst such steep and craggy mountains; but he was at last prevailed upon, by the earnest prayers and entreaties of all the chief officers of the army, to fall upon the enemy that very night. It was therefore agreed, that in the dead of the night all the trumpets should at once sound the charge, that this signal should be followed by an universal shout of the whole army, and that the soldiers should make what noise they could, by striking their spears against the brass vessels that were used in the camp. The king's army, at this sudden and unexpected noise, which was echoed again by the mountains, imagined at first that the gods themselves were come down from heaven to destroy them; and the Romans charging them on all sides with showers of stones and arrows from the tops of the hills, they took themselves to flight; but finding all the passes beset with strong bodies of horse and foot, they were forced to fly back into the valley, where, for many hours together, they were exposed to the enemy's missiles, without being able, in the confusion, either to attack them or defend themselves. They attempted indeed to make some resistance when the moon rose; but the Romans running down upon them from the hills, did not give them time to form in order, and the place was so narrow that they had not room even to make use of their swords. The king on that occasion lost ten thousand men according to Appian, and forty thousand according to Eutropius and others. On Pompey's side there fell between twenty and thirty private men, and two centurions.

Distress of Mithridates.

Mithridates, at the head of eight hundred horse, broke through the Roman army, and being after this effort abandoned by all the rest, because they were closely pursued by the enemy, he travelled all night, attended by three persons only, viz. his wife or his concubine, Hypsicratia, his daughter Dripetine, and an officer. At day-break he fell in with a body of mercenary cavalry, and three thousand infantry, who were marching to join him. By these he was escorted to the castle of Sinoria, situated on the borders of the two Armenias. As great part of his treasures was lodged here, he rewarded very liberally those who accompanied him in his flight; and taking six thousand talents, withdrew into Armenia. As soon as he passed the borders, he despatched ambassadors to Tigranes, acquainting him of his arrival; but that prince, who was then on the point of concluding a separate peace with the Romans, clapped his ambassadors in irons, pretending that his son Tigranes had, at the instigation of Mithridates, revolted first to the Parthians, and then to the Romans. Mithridates finding himself thus abandoned, even by his son-in-law, left Armenia; and directing his course towards Colchis, which was subject to him, and not as yet invaded by the Romans, passed the Euphrates the fourth day, and got safe into his own territories.

His flight into Scythia, and other countries.

Pompey sent out several parties in pursuit of the king, but remained himself with the main body of the army in the field of battle, where he built a city, calling it, from that remarkable victory, Nicopolis. This city, with the adjoining territory, he bestowed upon such of his soldiers as were old or disabled; and many flocking to it from the neighbouring countries, it in a short time became a very considerable place. This battle was certainly attended with very fatal consequences for Mithridates, who, his army being either entirely cut off or dispersed, was forced to abandon his own dominions, and fly for shelter to the most remote parts of Scythia. Pompey having concluded a peace with Tigranes, and settled the affairs of that kingdom, began his march in pursuit of Mithridates through those countries which are situated near the Caucasus. The barbarous nations through which he passed, chiefly the Albanians and Iberians, attempted to stop his march, but were soon put to flight. The excessive cold and the deep roads, however, obliged him to pass the winter near the river Cyrus. Early in the spring he pursued his march; but meeting with great opposition from the Iberians, a warlike nation, and entirely devoted to Mithridates, most part of the summer was spent in reducing them to subjection. In the mean time, Mithridates, who had wintered at Dioscurias, on the isthmus between the Euxine and Caspian Seas, and had there been joined by such of his troops as had made their escape from the late unfortunate battle, continued his flight through the countries of the Achæans, Zygians, Heniochians, Cercetans, Moschians, and Colchians. Of these nations some received him kindly, and even entered into alliance with him; whilst he was forced to fight his way through others with the sword.

Pompey's further conquests.

Pompey took the same route, directing his course by the stars, especially in the northern parts of Scythia, and even carrying with him a supply of water for the army in the vast deserts through which he marched. He spent two years in warring with these nations, and was often in danger of losing both his life and his army. But at last he overcame them all; and believing Mithridates, of whom he could obtain no account, to be dead, he marched back into Armenia Minor, where he allowed some rest to his soldiers, who were quite worn out with the hardships they had endured in the expedition. Having refreshed his army, he marched into Pontus to reduce some strongholds which were still garrisoned by the king's troops. Whilst he was at Aspis in Pontus, many of the king's concubines were brought to him; but he sent them all home to their parents, without offering them the least injury, and thereby gained the affections of the chief lords of Pontus, whose daughters they were. The strong castle of Symphori was delivered up to him by Stratonix, one of the king's concubines, upon no other terms than that he would spare her son Xiphares, who was with the king, in case he should fall into his hands. She likewise discovered to him treasures hidden under ground, which he, with great generosity, bestowed upon her, reserving for himself only some vessels to set off his triumph. Having taken another fort, called the *New Castle*, hitherto regarded as impregnable, he found in it great store of gold, silver, and other valuable things, which he afterwards consecrated to Jupiter Capitolinus. Here, in looking over the king's manuscripts, he came to discover where the rest of his treasures were concealed, what troops he could raise and maintain, and what sums were yearly paid him by his subjects and tributaries, so that he could form a true estimate of his whole power and wealth. Amongst other manuscripts, he found some books of physic, written by Mithridates himself, which he commanded Lenæas, a learned grammarian, to translate into Latin.

Mithridates appears again at the head of an army.

Pompey having thus reduced all Pontus, marched into Syria with a design to recover that kingdom, and, passing through Arabia, to penetrate as far as the Red Sea. But whilst he was employed in this expedition, accounts were brought him that Mithridates, whom he believed to be dead, had appeared unexpectedly in Pontus at the head of a considerable army, and surprised Panticapæum, a famous emporium at the mouth of the Euxine Sea. All this time he had lain concealed in the territories of a Scythian prince, adjoining to the Palus Mœotis; but hearing that Pompey had left Pontus, and was engaged in other wars, he ventured out of his hiding-place, resolved either to recover his paternal kingdom, or perish in the attempt. He returned privately into Pontus, and managed matters there so dexterously that the Roman garrisons knew nothing of his arrival till he appeared with a considerable army in the field. He advanced first to the castle of Symphori; and understanding that Stratonix had delivered it up to Pompey, on condition that he would save the life of her son in case he should take him prisoner, the king immediately caused the youth, who was in his army, to be put to death, and his body to be left unburied; Stratonix beholding from the walls the cruel and unnatural murder, for he was her son by Mithridates, and had served him with great fidelity. At the same time he sent ambassadors to Pompey to treat of a peace, offering to pay a yearly tribute to the republic, upon condition of being restored to his kingdom. Pompey replied, that he would hearken to no proposals whatsoever, unless the king came to treat with him in person, as Tigranes had done. But this Mithridates looked upon as nowise consistent with his dignity, and therefore, laying aside all thoughts of an accommodation, he began to make what preparations he could for renewing the war.

Recovers several places.

He summoned all his subjects who were able to bear arms to meet at an appointed place; and having chosen out of the whole multitude sixty cohorts, each consisting of a hundred men, he incorporated them with the regular troops that were already on foot. Being now in a condition to act offensively, for Pompey had left but a small number of troops in Pontus, he possessed himself of Phanagorium, Chersonesus, Theodosia, Nymphæum, and several other important places. But, in the mean time, Castor, whom Mithridates had appointed governor of Phanagorium, falling out with Tripho, one of the king's favourite eunuchs, killed him, and, dreading the king's resentment, stirred up the inhabitants to a revolt. By this means Phanagorium was again lost; but the castle, which was defended by four of the king's sons, Artaphernes, Darius, Xerxes, and Oxathres, held out for some time. The king hastened to their relief; but the castle being set on fire by the rebels, they were forced to surrender to Castor before his arrival. These four sons, with one of the king's daughters, by name Cleopatra, Castor sent to the Romans; and fortifying himself in the town, persuaded most of the neighbouring cities, which were oppressed with heavy taxes, and greatly harassed by the king's collectors, to join in the rebellion.

Discontent of his subjects.

Mithridates finding that he could neither rely upon the soldiery, most of whom were forced into the service, nor on his other subjects, who were dissatisfied by reason of the exorbitant taxes, sent ambassadors to invite the princes of Scythia to come to his relief, and with them his daughters, to be bestowed in marriage on such as showed themselves most inclined to assist him. But as the ambassadors he employed on this occasion were eunuchs, a race of men no less abhorred by the army than favoured by the king, over whom they had a great ascendant, especially in his old age, the soldiers who were sent to attend them on their journey put them all to the sword as soon as they were out of the king's reach, and delivered his daughters up to the Romans. Mithridates, finding himself thus deprived of his children, betrayed by his army, and forsaken even by those on whom he chiefly relied, could not yet be induced to submit to the Romans, though Pompey promised him honourable conditions, provided he came to treat with him in person.

His design of invading Italy.

In this desperate condition he left no stone unturned to stir up the princes of Asia against the Romans, especially the Parthians; but finding them awed by the great opinion they all had of Pompey, he had recourse at last to the European Gauls, whom he understood to be at war with the Romans; and having sent some of his trusty friends to engage them in his favour, taking leave of his own kingdom, he began his long march, designing to pass through Bosphorus Cimmerius, Scythia, and Pannonia, and, joining the Gauls, to pass the Alps, and invade Italy. This design was no sooner known in the army, than the soldiers openly began to complain and mutiny; exaggerating the boldness of the attempt, the length of the march, and the insurmountable difficulties which must necessarily attend such a desperate enterprise. The chief commanders did all that lay in their power to divert him from it; representing to him, that if he was not able to cope with the Romans in his own kingdom, much less would he be a match for them in Italy or Gaul, where they could daily receive new supplies; whereas he would lose the greater part of his army in so long and difficult a march, and the rest, perhaps, in the first engagement, without any possibility of repairing the loss. But all was to no purpose. They found him so unalterably fixed in his resolution, that he caused those to be put to death who with most warmth remonstrated against it, not sparing even his own son Exipodras, for dropping some unguarded expressions on that occasion. Thus they were forced to let him pursue his own measures, until they found a more proper opportunity to oppose them, which soon afterwards presented itself, as they were encamped at Bosphorus Cimmerius, on their march into Scythia.

evolt of is son harnaces.

Here Pharnaces, the king's favourite son, whom he had appointed to succeed him, observing the general discontent that reigned in the army, began to entertain thoughts of placing the crown on his own head; and not doubting but the soldiery would stand by him, if he declared against the intended expedition into Italy, openly protested amongst the Roman deserters, who were a considerable part of the army, that if they would follow him he would return into Pontus. The Romans, who were well apprised of the danger that attended such an undertaking, and had most of all exclaimed against it, promised to support him to the utmost of their power, and even encouraged him to assume the title of king, a title which his father seemed determined to hold till he had destroyed, by his rash and desperate attempts, himself, his friends, and his army. Pharnaces, finding he could depend upon the Romans, engaged the same night most of the principal commanders in his party, and by their means the greater part of the soldiery. It was agreed, that next morning by break of day all those who had declared in his favour should appear in arms, and with a loud shout proclaim Pharnaces king. This was accordingly done, and the shout returned even by those persons whom Pharnaces had not thought proper to let into the secret. The king, who had taken up his quarters in the city, being awakened by the noise, sent out some of his domestics to ascertain what had happened in the army. Neither did the officers or soldiers dissemble the matter, but boldly answered, that they had chosen a young king instead of an old dotard governed by eunuchs.

Hereupon Mithridates, mounting on horseback, and attended by his guards, went out to appease the tumult; but his guards forsaking him, and his horse being killed under him, he was obliged to fly back into the city, whence he sent several of his attendants one after another to desire of his son a safe-conduct for himself and his friends. But as none of the messengers returned, some being slain, and others siding with the new king, Mithridates endeavoured to move his son to compassion, by signifying to him from the walls the distressed condition to which he was reduced by a son whom he had favoured above the rest of his children; but finding him nowise affected by this speech, turning to the gods, he besecched them with many tears to make his son know one day by experience the grief and agony which a father must feel in seeing his love and tenderness requited with such base and monstrous ingratitude. Having thus spoken, he thanked in a very obliging manner those who had stood by him to the last, and exhorted them to make their submission to the new king on the best terms they could procure; adding, that as for himself, he was determined not to outlive the rebellion of a son whom he had always distinguished with particular marks of paternal affection.

ath of thrida-

After this, he withdrew into the apartment of his wives and concubines, where he first took poison himself, and then presented it to them, and to his favourite daughters Mithridatis and Nissa, who not long before had been betrothed to the kings of Egypt and Cyprus. To the women it proved immediate death; but on the king, who from his infancy had inured his constitution to poisonous potions, it had so slow an operation, that he was forced, through fear of falling into the rebels' hands, to recur to his sword. Neither did the wound, as he was greatly weakened by the poison, prove mortal; so that the rebels, having in the mean time stormed the town, and broken into the house, found the king wallowing in his blood, but still alive, and in his senses. Pharnaces, hearing this, sent some of those that were about him to dress his wounds, with a design to deliver him up to the Romans, and thereby ingratiate himself with Pompey. But, in the mean time, a Gaul, who had served in the army, by name Bitætus, or Bithocus, entering the king's room in quest of booty, and being touched with compassion at seeing him forsaken by all his friends, and struggling on the bare ground in the agonies of death, drawing his sword, put an end to his misery, and thus prevented the insults which he apprehended if he should fall alive into his son's hands. The barbarian, when he first saw the king, is said to have been so awed by the majesty of his countenance, that, forgetful of his booty, he fled out of the room; but being called back, and earnestly entreated by the dying prince to put an end to his misery, he summoned all his courage to perform that office, which he did with a trembling hand; and immediately retired without touching anything that belonged to the king, though the hope of a rich booty was the only motive that had led him thither.

Excessive joy of the Romans at his death.

Pompey, who was at that time engaged in a war with the Jews, received the first notice of the death of Mithridates, as he was on his march to Jerusalem. The messenger who brought the joyful tidings was sent by Pharnaces, and appeared unexpectedly before Pompey with the branch of a laurel, as was customary on the like occasions, twisted round the head of his javelin. When he heard what had happened at Panticapæum, he was so impatient to impart it to the soldiery, that he could not even wait until they had raised him a mount of turf from which to address the army, according to the custom of the camp, but ordered those who were beside him to form a kind of mount with their saddles; and from thence he acquainted the soldiery that Mithridates had laid violent hands on himself, and that his son Pharnaces was ready to acknowledge the kingdom as a gift of the people of Rome, or resign it if they were unwilling he should reign. This news was received with joyful shouts by the whole army, and the day solemnized with feasts and sacrifices throughout the camp, as if in Mithridates alone all the enemies of the republic had expired. Pompey despatched without delay a messenger with letters to the senate, acquainting them with the death of Mithridates, and the submission of his son Pharnaces. When his letters were read, the senators were so overjoyed, that, at the proposal of Cicero, then consul, they appointed twelve days for returning due thanks to the gods, who had delivered them from such an insulting and powerful enemy: and the tribunes of the people enacted a law, by which Pompey, in consideration of his eminent service in the Mithridatic war, was to wear a crown of laurel, with the triumphal gown at the Circensian games, and a purple gown at the scenical shows.

Submissive embassy of Pharnaces.

Pharnaces, when he heard of his father's death, caused his body to be preserved in brine, proposing to present it to Pompey, who had promised to return into Pontus after the reduction of Judæa, and there settle matters to his satisfaction. Accordingly, the latter, having taken the city and temple of Jerusalem, set out with two legions for Pontus; and on his arrival at Sinope, he was there met by ambassadors from Pharnaces, acquainting him that their master had forborne assuming the title of king till his will and pleasure were known; that he put both himself and the kingdom entirely into his hands; and that he was willing to attend him at any time or place which he might think fit to appoint. The same ambassadors delivered up to Pompey those who had taken Manius Aquilius the Roman legate, whom Mithridates had put to a cruel death; all the prisoners, hostages, and deserters, whether Romans, Greeks, or barbarians; and the body of Mithridates, with his rich apparel and arms, which were greatly admired by Pompey and the other Romans. Both soldiers and officers flocked to see the king's body; but Pompey declined that sight, saying that all enmity between that great prince and the people of Rome had ended with his life, and, returning the body to the ambassadors, caused it to be interred with the utmost pomp and magnificence amongst his ancestors in the burying-place of the kings of Pontus, the Roman commander defraying all the charges of the ceremony. With the body Pompey restored his wearing apparel and armour; but the scabbard of his sword, which cost four hundred talents, was stolen by Rublius, a Roman, and sold to Ariarathes king of Cappadocia; and his cap or turban, which was a curious piece of workmanship, was privately taken by one Caius, who presented it to Faustus the son of Sylla, in whose house it was kept, and shown for many years afterwards amongst the rarities which Sylla had brought out of Asia.

The kingdom of Bosphorus bestowed on Pharnaces.

Pompey bestowed the kingdom of Bosphorus on Pharnaces, and honoured him with the title of friend and ally of the people of Rome. Pharnaces, being thus acknowledged king of Bosphorus, sent orders to all the garrisons of Pontus to submit themselves, delivering up the castles and treasures with which they had been intrusted, to Pompey, who by that means amassed an immense booty. In the city of Talaura, which Mithridates used to call his wardrobe, he found two thousand cups of onyx set in gold, with such store of gold and silver vessels, of costly furniture, of saddles, bridles, and trappings, set with jewels and precious stones, that the Roman commissaries spent thirty days in taking an inventory of the whole. Nor was this all. In another castle he found three large tables with nine salvers of massive gold, enriched with precious stones to an inestimable amount; the statues of Minerva, Mars, and Apollo, of pure gold and most curious workmanship; and a pair of gaming-tables of two precious stones, three feet broad and four feet long, on which was a moon of gold weighing thirty pounds, with their pieces, all of the same precious stone. In a fort situated amongst the mountains, were also delivered up to him the king's statue of massive gold, eight cubits high, his throne and sceptre, and the bed of Darius the son of Hystaspes. Most of these treasures had been transmitted to him from his ancestors, chiefly from Darius king of Persia; some belonged to the Ptolemies of Egypt, and had been deposited by Cleopatra in the hands of the Coans, who delivered them to Mithridates; and great part of them had been collected by the king himself, who was very fond of rich and stately furniture.

Pompey having thus got entire possession of Pontus, and reduced it to the form of a Roman province, marched into Asia properly so called; and having wintered at Ephesus, he early in the spring set out for Italy with a fleet of seven hundred ships. As he brought over his army with him, the senate was under no small apprehension lest he should make himself absolute, and rule without control. But he had no sooner landed at Brundusium, than he disbanded the army, without waiting for any decree either of the senate or people; a proceeding which neither his friends nor his enemies had expected. His triumph lasted two whole days; and although he was attended in his triumphal chariot by three hundred and twenty-four captives of distinction, amongst whom were five sons and two daughters of Mithridates, yet he would not suffer any of them to be put to death, as had been done by others, but sent them all back, except such as were of royal extraction, to their respective countries, and even supplied them with money to defray the charges of their journey. After his triumph, he delivered into the treasury twenty thousand talents, though, at the disbanding of the army, he had divided sixteen thousand talents amongst the tribunes and centurions, two thousand sestertia amongst the quæstors, and had given to each soldier fifty sestertia.

Quarrel of Pharnaces with the Romans.

Pompey had no sooner left Asia, than Pharnaces fell unexpectedly upon the Phanagorenses, a people of Bosphorus, whom Pompey had declared free, because they had been the first to revolt against his father Mithridates, and by their example had induced others to abandon the king's party. Pharnaces besieged their chief city Phanagoria, and kept them blockaded till, for want of provisions, they were forced to sally out, and put all to the issue of a battle; and this proving unsuccessful, they delivered up themselves and the city to the conqueror. Some years afterwards, when the civil war broke out between Cæsar and Pompey, he laid hold of that opportunity to recover the provinces which his father had formerly possessed; and, having raised a considerable army, overran Pontus, Colchis, Bithynia, Armenia, and the kingdom of Moschis, where, as Strabo observes, he plundered the temple of the goddess Leucothea. He took the strong and important city of Sinope, but failed to reduce Amisus. In the mean time, Cæsar, having vanquished Pompey and his party, appointed Cn. Domitius Calvinus governor of Asia, enjoining him to make war upon Pharnaces with the legions which were quartered in that province. Domitius immediately despatched ambassadors to Pharnaces, commanding him to withdraw his troops from Armenia and Cappadocia. The king returned for answer, that he was willing to abandon Cappadocia; but as to the kingdom of Armenia Minor, it was part of his hereditary dominions, and therefore he would not resign it till he had an opportunity of laying his pretensions before Cæsar himself, whom he was ready to obey in all things. Hereupon Domitius, drawing together all the forces he could collect, marched into Cappadocia, which he recovered without opposition, Pharnaces having abandoned it to make a stand in Armenia, which lay nearer his own dominions. Domitius pursued him thither, and having overtaken him near Nicopolis, found his army drawn up in battle array, and the king ready to come to an engagement.

Romans defeated.

As Domitius did not decline the combat, both armies advanced, and the king, at the head of a chosen body of men, fell upon the left wing of the Romans, consisting mostly of raw and undisciplined Asiatics; and having with little difficulty put them to flight, he penetrated to the centre, where the thirty-fifth legion, after a faint resistance, gave ground, and, retiring to the neighbouring mountains, left their allies to shift for themselves. The latter were all cut off, and Domitius, with the remains of his scattered army, marched back into Cappadocia, and thence, winter being now at hand, into the province of Asia. The king, elated with this victory, and hearing that Cæsar, with the flower of the Roman forces, was engaged in the siege of Alexandria, appointed Asander governor of Bosphorus, and marched into Cappadocia in pursuit of Domitius, with a design of invading Asia, and recovering all the provinces which had once been subdued by his father. Bithynia and Cappadocia readily submitted; but Armenia the Lesser, which was held by Dejotarus, made so vigorous a resistance that he was forced to abandon the enterprise, lest the Romans should in the mean time strengthen themselves in Asia, whither he was in haste to march, in hopes of meeting there with the same success as his father Mithridates had done. But before he reached that province, he was informed that Asander had revolted, in hopes of gaining the favour of the Romans, and obtaining from them the kingdom of Bosphorus for himself. At the same time, he received intelligence that Cæsar, having at last reduced Alexandria, and settled the affairs of Syria, was marching into Armenia.

tempt outwit lius Cæ-

Pharnaces, being not a little dismayed at this news, immediately despatched ambassadors to sue for peace, hoping that Cæsar, who was hastening into Italy with a design to pass into Africa, would willingly listen to any proposals of a pacific nature. Cæsar courteously entertained the ambassadors; and though he did not intend to agree to their conditions, yet, that he might come upon Pharnaces unawares, he showed himself very desirous of entering into a treaty of peace. But nevertheless he pursued his march with all possible expedition; and, arriving on the confines of Pontus, ordered all the troops that were quartered in the neighbouring provinces to join him; having brought from Alexandria only one legion, namely, the sixth, and that consisting of only a thousand men. Besides this veteran legion, he found at the place of general rendezvous three others, but all of them very indifferently armed, and worse disciplined. With these forces, however, such as they were, he advanced against Pharnaces, who being greatly frightened at his approach, by reason of the success which had attended him in all his expeditions, again despatched ambassadors with a crown of gold, offering him his daughter in marriage, and promising to do whatever he should require. The ambassadors took care to let him know, that their master, though highly obliged to Pompey, yet had never been prevailed upon to send him any supplies during the civil war, as had been done by Dejotarus, king of Armenia the Lesser, whom he had honoured with his friendship. Cæsar returned for answer, that he was willing to conclude a peace with Pharnaces, provided he retired without delay from Pontus, restored all the captives and hostages, whether Romans or their allies, and give back the goods of the Roman citizens and publicans which he had seized since he first took up arms. He added, that as to his not sending supplies to Pompey, they ought rather to have concealed such an ungrateful proceeding of their master, than alleged it as any merit, since the forsaking of one to whom he was indebted for his crown bespoke him a man of mean, selfish, and unworthy principles.

feat of rnaces.

Pharnaces, on the return of his ambassadors, acquainted Cæsar that he agreed to the conditions; but finding that Cæsar's affairs called him into Italy, he required a longer period of time for the performance of what was stipulated between them, starting daily new difficulties, in hopes that Cæsar would in the mean time be obliged to depart, and leave the affairs of Pontus in the same posture in which he had found them. Cæsar, disgusted at these evasions, and unable any longer to brook the king's deceitful behaviour, determined to put himself at the head of his army, and attack the enemy in his camp when he least expected it. Accordingly, having marched out in the night, he came by break of day in sight of the king's army; and uttering these words, "Shall this treacherous parricide go unpunished?" broke into the camp at the head of a thousand horse. The king's chariots, which were armed with scythes, caused some small disorder amongst Cæsar's horse; but in the mean time the rest of his army coming up, he put the enemy to flight, and obtained a complete victory. This battle was fought near the place where Mithridates had routed with great slaughter the Roman army under the command of Triarius. Most of the king's army were either taken or cut in pieces; but Pharnaces himself had the good luck to make his escape whilst the Romans were occupied in plundering the camp. This victory was so quickly decided, that Cæsar, in a letter to his friend Anitius, at Rome, expressed it in three words; "I came, I saw, I conquered." He ever afterwards used to call Pompey a fortunate rather than a great commander, since he had gained his chief glory in the Mithridatic war, fighting with so cowardly an enemy. He divided amongst his soldiers the rich booty and the spoils of the camp; and because Mithridates had erected a trophy near that place as a monument of his victory over Triarius, which, as it was consecrated to the gods, Cæsar did not think lawful to pull down, he set up another over against it, to transmit to posterity his victory over Pharnaces. After this victory he recovered and restored to the allies of the Roman people all the places which Pharnaces had made himself master of during the war, declared Amisus a free city, and appointed Mithridates Pergamenus king of Bosphorus instead of Pharnaces.

Death of Pharnaces.

Having thus settled the affairs of Pontus, he set sail for Italy, leaving Domitius Calvinus to pursue the war against Pharnaces if he should again appear in the field. After the battle, Pharnaces had retired to Sinope with a thousand horse, where he was quickly besieged by Domitius, to whom he surrendered the town, upon no other condition than that he should be suffered to retire into Bosphorus with the small body that attended him. This Domitius willingly granted, but caused all the king's horses to be killed, since he had asked a safe conduct only for his horsemen. With these and a band of Scythians and Sarmatians he attempted to recover the kingdom of Bosphorus; but being met between Theodocia and Panticapæum, both which cities he had reduced, by Asander, who was still in possession of the kingdom, a sharp engagement ensued, in which the king's men, not being used to fight on foot, were put to flight, and Pharnaces himself, who remained alone in the field, was surrounded by the enemy, and cut in pieces, after having reigned in Bosphorus Cimmerius, the kingdom which Pompey had bestowed upon him, fifteen or sixteen years.

Pontus again made a kingdom by Antony.

Upon the death of Pharnaces the kingdom of Pontus was again reduced into the form of a province, and so continued till the triumvirate of Antony, who, after the battle of Philippi, conferred it upon Darius the son of Pharnaces, for his services during the civil war. He continued faithful to the Romans, but during his reign performed nothing worth mentioning.

Polemon.

Darius was succeeded in the kingdom by Polemon, who was likewise preferred to that honour by Mark Antony. He was the son of Zeno, an orator of Laodicea, and greatly favoured by Antony. From him that part of Pontus which borders on Cappadocia derived the name of *Polemonaicus.* He attended Mark Antony in his expedition against the Parthians; and being taken prisoner in the unsuccessful battle fought by Statianus, he was sent by the king of the Medes, an ally of the Parthians, to conclude a peace with the Romans. In this embassy he acquitted himself so well that Antony added the kingdom of Armenia to his other dominions. In the war between Antony and Augustus he joined the former; but after the battle of Actium he was received into favour by the latter; and being sent by Agrippa against Scribonius, who, upon the death of Asander had usurped the kingdom of Bosphorus, he overcame him, and reduced the kingdom of Colchis, which was bestowed upon him by Agrippa, who likewise honoured him with the title of "friend and ally of the people of Rome." He afterwards waged war with the neighbouring barbarians refusing to live in subjection to the Romans; but was overcome, taken, and put to death, by the Aspungitani, a people bordering on the Palus Mœotis.

Polemon II.

Upon his death, his son Polemon II. was by the Emperor Caligula raised to the throne of Bosphorus and Pontus. But the emperor obliged him to exchange the kingdom of Bosphorus for part of Cilicia; and Nero, with his consent, reduced that part of Pontus which he enjoyed into the form of a province. He fell in love with Berenice, daughter of Agrippa, king of Judæa; and in order to marry her he embraced the Jewish religion. But as she soon became tired of his riotous way of living, and returned to her father, so he renounced his new religion, and again embraced the superstitions of paganism. Polemon dying without issue, the ancient kingdom of Pontus was parcelled out into several provinces, and added to those of Bithynia, Galatia, and Cappadocia, that part of it only which was called *Pontus Polemonaicus* retaining the dignity of a distinct and separate province. During the civil discords between Vespasian and Vitellius, Anicetus, first a slave, afterwards freedman of Polemon, and lastly commander of the royal navy, took up arms with the design of rescuing the kingdom from the Roman yoke; and, being joined by great multitudes drawn together by the prospect of spoil, overran the country, and possessed himself of Trapesund, a city founded by the Grecians on the utmost confines of Pontus. Here he cut in pieces a cohort formed of the inhabitants, but which had been formerly invested with the privilege of Roman citizens. He likewise burned the fleet, and, Mucianus having called to Byzantium most of the Roman galleys, swept the seas. Hereupon Vespasian, who at that time was in Syria, sent Verdius Gemnius into Pontus with a chosen body of auxiliaries from the legions. The latter having assailed the enemy whilst they were in disorder, and roaming about in pursuit of prey, drove them into their vessels; then with some galleys chased Anicetus into the mouth of the river Chobus, where he thought himself safe under the protection of Sedochus, king of the Lazians, whose alliance he had purchased by large sums and rich presents. Sedochus at first refused to deliver him up to the Romans; but was soon prevailed upon, partly by threats, and partly by presents, to surrender both him and all the other fugitives who had taken sanctuary in his dominions. Thus ended that servile war; and the kingdom of Pontus continued to be a province of the empire till the time of David and Alexis Comnenus, who being driven from Constantinople by the French and the Venetians in the year 1204, under the command of Baldwin earl of Flanders, settled, the one at Heraclea, and the other at Trebisond. The troubles which arose amongst the Latins gave Alexis Comnenus an opportunity of erecting here a new empire, which comprehended great part of Pontus, and was known by the name of the Empire of Trebisond. The Comneni held it about 250 years, till the time of Mahommed II. who carried David Comnenus, the last emperor of Trebisond, prisoner to Constantinople, in the year 1462, with all his family, and subjected his empire to that of Constantinople.

PONTYPOOL, a market-town of the county of Monmouth, in the parish of Trevethan, and hundred of Abergavenny, 150 miles from London. It is situated at the foot of a range of hills profusely rich in coal and iron. It was formerly celebrated for its japan ware; but that trade has been in some degree superseded by similar manufactures at Birmingham, whilst the trade in iron and coal has vastly extended, and increased the population within the last forty years. The population of the whole parish amounted in 1801 to 1472, in 1811 to 2423, in 1821 to 3931, and in 1831 to 10,280.

PONZA, or PONTIA, is the name of a small island of the Tuscan Sea, well known as the place to which many illustrious Romans were banished. It is situated on the coast of Italy, near Terracina, and in the neighbourhood of other small islands or rocks. All these islands were visited by Sir William Hamilton in the year 1785; and an account of his journey is given in a letter to Sir Joseph Banks, which appeared in the Philosophical Transactions (vol. lxxvi. p. 365). Sir William arrived at Ponza on the 20th of August; and, according to his account, it is situated about thirty miles from Ventotienne. On the 21st he went round it in a boat. Its length is about five miles, but its breadth is nowhere above half a mile, and in some places not more than five hundred feet. It is surrounded by a multitude of detached rocks, some of them very high, and most of them composed of a compact lava. There are many irregularly-formed basalts, but none in large columns. In some places they have a reddish tinge, from iron ochre, are very small, and irregularly laid over one another. Some stand perpendicularly, others obliquely, and some lie horizontally. The rocks themselves in which these masses are found are lava of the same nature with the basalts. At first sight they appear like the ruins of ancient Roman brick or tile buildings. One rock is composed of large spherical basalts, and in other places our author found the lava inclined to take the like spherical form, though on a much smaller scale, some of the former basalts being nearly two feet in diameter. All these rocks, in our author's opinion, have been detached by the sea from this island, which is entirely composed of volcanic matter, lavas, and tufas of various qualities and colours, as green, yellow, black, and white. Some of these matters are more compact in their texture than others; and in some parts great tracts seem to have undergone similar operations, which still subsist at a spot called the Pisciarelli, on the outside of the Solfatara, near Puzzoli, and where a hot sulphureous vitriolic acid vapour converts all which it penetrates, whether lavas, tufas, volcanic ashes, or pumice-stones, into a pure clay, mostly white, or with a tint of red, blue, green, or yellow.

In one part of this island there is a sort of tufa remarkably good for the purpose of building. It is as hard as Bath-stone, and nearly of the same colour, without any mixture of lava or pumice-stone, which usually abounds in the tufas of Naples, Baiæ, and Puzzoli.

The island of Palmarole, which is about four miles from Ponza, is not much more than a mile in circumference. It is composed of the same volcanic matter, and probably was once a part of Ponza; but, in our author's opinion, it looks as if the island of Zannone, which lies about the same distance from Ponza, was once likewise a part of the same; for many rocks of lava rise above water in a line between the two last-mentioned islands, and the water there is much more shallow than in the Gulf of Terracina.

Zannone is much larger and higher than Palmarole, and the half of it next the continent is composed of a limestone similar to that of the Apennines near it, whilst the other half is composed of lavas and tufas, resembling in every other respect the soil of the islands just described. Neither Palmarole nor Zannone are inhabited; but the latter furnishes abundance of brushwood for the use of the inhabitants of Ponza, whose number, including the garrison, amounts to near 1700. The uninhabited island of St Stefano in like manner furnishes wood for the people of Ventotienne. It is probable that all these islands and rocks may in time be levelled by the action of the sea. Ponza, in its present state, is the mere skeleton of a volcanic island; little more than its hard or vitrified parts remaining, and these seem to be slowly and gradually mouldering away. The governor of the castle of Ponza, who had resided there fifty-three years, informed our author that the island was still subject to earthquakes; that there had been one violent shock there about four years before, and that the most violent one he ever felt was on the very day and at the very hour when Lisbon was destroyed. Two houses out of three which were then on the island were thrown down. "This," says our author, "seems to prove that the volcanic matter which gave birth to these islands is not exhausted."

POOGUL, a small town of Hindustan, in the province of Mooltan and district of Bikaneer, in the midst of a sandy desert. It has several brackish wells, and some reservoirs of good rain-water vaulted over with brick, from the sale of which to travellers parched with thirst the inhabitants derive a precarious income. They also rear camels and a few goats. It is twenty-four miles north-west of Bikaneer.

POOL, a seaport of the county of Dorset, within the hundred of Cogdean, and a county of itself, 106 miles from London. It is situated on a peninsula stretching into a large estuary at the mouth of the river Froome; and vessels drawing sixteen feet water can approach the quays. The mouth of the estuary is defended by a castle on the island of Browsea; and near it, in Studland Bay, as well as in Swanage Bay, there is good anchorage. The chief pursuits are the fishery and the trade with Newfoundland, that give occupation to more than 200 sail of vessels, which repair to that island and load with salted cod and other fish, a few for England, but mostly for the ports of Spain, Portugal, and the Mediterranean; and the latter return with the productions of the several countries where they sell their fish. There is, besides, a considerable coasting trade, especially for coals; and within the estuary and under the port, at a place called Russell's Quay, the greater part of the best pipe-clay, which is dug near it, is shipped for the use of the manufacturers of china and pottery in Staffordshire. It must have been a considerable port in the time of the Romans, as one of their roads may be traced from Winchester to Pool. The town is incorporated, and is governed by a mayor, who is an admiral within the port, and holds an admiralty court, a recorder, sheriffs, and aldermen, together with eighteen councillors. Till of late years one of the judges on the western circuit went to Pool to try criminals, but they are now tried at Dorchester. The town returns two members to parliament. The markets are held on Monday and Thursday. The old part of the town is ill built, but many houses recently erected are good. The population amounted in 1801 to 4761, in 1811 to 4816, in 1821 to 6390, and in 1831 to 6459.

POOLE, Matthew, a very learned writer in the seventeenth century, was born at York in 1624. He was educated at Emmanuel College, Cambridge, and afterwards incorporated in the university of Oxford. He succeeded Dr Anthony Tuckney in the rectory of St Michael de Quern, in London, about 1648. In 1658 he set on foot a project for maintaining youths of great parts at the universities, and was honoured with the approbation of the heads of houses in both of them. He solicited the affair with so much vigour, that in a short time L.900 per annum was procured for that purpose; but this design was laid aside at the Restoration. In 1662 he was ejected from his living for nonconformity. He was ten years employed in composing his *Synopsis Criticorum;* and, besides this great work, he published several other pieces. When Titus Oates's depositions concerning the popish plot were printed, our author found his name in the list of those who were to be cut off, so that he was obliged to retire to Holland, where he died in 1679, leaving behind him the character of a very able critic and casuist.

POONAH, a city of Hindustan, in the province of Bejapore, and capital of the peshwa, the chief of the Mahratta state. Situated about thirty miles to the east of the Ghauts, it is an open and defenceless town, covering little more than two square miles, and indifferently built, so that it has rather the appearance of a large village than that of a town. It has long and narrow streets, and the houses are indifferently built; the better sort are raised with large blocks of granite to the height of about fourteen feet, after which the superstructure is composed of timber frames, with slight brick-walls. The ordinary houses are only one story high, with tiled roofs. The lime which cements the bricks and tiles is so bad, that the rain washes away any building that does not depend on timber for its support. There is an ancient palace or castle, in which the peshwa's brother and other members of the family reside; it is surrounded by high and thick brick walls, with round towers at the angles, and has only one entrance through a pointed arch. Here the peshwa assembles the Brahmins, to whom he gives alms at the great feast when the rainy season terminates, and who are accustomed on this occasion to beg their way to Poonah from all parts of India. The family of the peshwa have, besides the castle, a modern house for their own residence in another part of the town. In 1809 the peshwa made arrangements for the erection of a palace, to be built by British architects. Poonah was, in the flourishing period of the Mahratta power, a great place of rendezvous for the different independent chiefs, with their numerous followers, in order to consult on the general interests of the confederacy, and, when at war, to settle the plan of operations. These meetings were held about the middle of October, at the end of the rainy season, and were sometimes attended by 400,000 or 500,000 people, who were encamped in the surrounding plain, and were well supplied with every necessary, such as wood, grain, and fodder, which were brought down the rivers. The inhabitants are well provided from extensive markets; and in one long street a great variety of articles are displayed, such as mirrors, globes, lamps, &c. The slaughter of kine is prohibited; and poultry is never reared or eaten except by the very lowest castes. The streets are named after mythological personages, with the addition of *warry*, which is equivalent to street. Poonah is situated at the confluence of the Moota with the Moola River, their union forming the Mootamoola, which runs into the Beemah; the latter river forms a junction with the Krishna, and, during the rainy season, a journey by water may be effected from within seventy-five miles' distance of the western coast of India to the Bay of Bengal. The Moola washes the city on the north side, where it is two hundred yards in breadth, and in the dry season very shallow. In one of the suburbs, called the Sungum, situated on the opposite side of the Moota River, about two miles from the city, the British ambassador with his suite resides, and other British subjects. The cantonments for the subsidiary force are also in this vicinity. Mythological excavations are found to the eastward of the city, but greatly inferior to those of Elora and Elephanta. The practice of sacrificing the widow along with the deceased husband was common at Poonah, and this cruel and barbarous rite was performed at the confluence of the Moota and Moola Rivers, held sacred by the Hindus, and close to the British residency. The burning of widows is now declared a crime by the British government, and is prevented by the interference of the civil power; so that these enormities under the name of religion can no longer be practised under the eye of the British authorities. The population of Poonah is estimated at 100,000, on the most moderate computation.

The first notice of Poonah occurs in the early part of the seventeenth century, when it was included in the jaghire or estate of Thahjee, father of the famous Sevajee, who built the palace there for his own residence. In 1740 the office and the power of the peshwa was usurped by Bajeerow, who having confined his master Ram Rajah to the fortress of Sattara, fixed his residence at Poonah, and died there in 1759. The dignity was transmitted to his grandson Madhoorow, who died in 1772, and was succeeded by his son Narrain Row, who was murdered by his uncle Ragoba; and shortly afterwards a posthumous child of the deceased was placed on the throne. He died in 1795, and the elder of the two sons of Ragoba, named Bageerow, succeeded. During these disputes Scindia and Holkar interfered, and seized the sovereignty. A treaty was in consequence concluded between the peshwa and the British, who re-established his authority; and this good understanding continued for nearly fifteen years. But in 1817, the peshwa, anxious to emancipate himself from the bondage of the British yoke, entered into the hostile combination which was then formed amongst the native powers for the assertion of their independence. As the contest ended in the triumph of the British armies, the peshwa was compelled to fly, and, after a contest of nearly two years, he at last consented to resign his office, and to retire on a pension to Benares. A descendant of Ram Rajah was raised to the nominal dignity of the peshwa, now become a mere pageant, and a pensioner on the British, on condition of his residing at Sattara; and a British resident, denominated a commissioner, is now stationed at Poonah. The travelling distance from Bombay is 98 miles, from Hyderabad 387, from Oojain 442, from Nagpoor 486, from Delhi 913, and from Calcutta by Nagpoor 1208 miles. Long. 74. E. Lat. 18. 30. N.

POONAKHA, a town of Northern Hindustan, in the province of Bootan, and situated on the Chantchieu River. It is the winter residence of the Deb rajah, and the warmest part of Bootan, and is therefore selected for the cultivation of exotics. The palace is adorned with a handsome gilt canopy. Long. 89. 45. E. Lat. 27. 56. N.

POONAR, a town and district of Hindustan, in the province of Berar, and territory of the nizam. The district is mountainous and woody, and is situated between the twenty-first and twenty-second degrees of north latitude. The town is seventy-five miles south from Gluckpoor. Long. 78. 13. E. Lat. 20. 9. N.

POONDY, a seaport town of Hindustan, in the province of the Northern Circars, and district of Cicacole, situated on a small river capable of being entered by boats, which thereby escape the surf so dangerous along this coast. Long. 84. 27. E. Lat. 18. 40. N.

POOR, in law, an appellation given to all those who are in such a low and mean condition that they either are or may become a burden to the parish.

POORBUNDER, a town of Hindustan, on the south-west coast of the Gujerat peninsula. An agreement was concluded in 1808, between the Bombay government and the Rana Sertanjee and Coer Hallajee of Poorbunder, not to connive at any act of piracy committed by any person under their authority. Long. 69. 50. E. Lat. 21. 37. N.

POOR KNIGHTS, a cluster of islands in the Southern Pacific Ocean, near the north-eastern coast of New Zealand. Long. 174. 42. E. Lat. 35. 30. S.

POOR-LAWS.

Until very recently, the great interest felt in the body of laws comprehended under the above title, was derived from the consciousness of the danger with which the manner of their administration in England threatened the property of the rich, and the morality of the whole people. As the law continues fundamentally the same as it was before the adoption of an improved administration, that source of interest in these institutions remains; but the present sense of security renders possible a calmer and more dispassionate examination of their merits and demerits than could previously to the year 1834 have been made by the most candid persons acquainted with the rapid progress of the evils of the system.

Origin and objects of poor-laws.

It was generally, and is now frequently, assumed by English writers, that a legal system of compulsory relief to the poor was peculiar to the polity of England. No assumption could be less justified by the facts, as will presently be shown. Wherever inquiry has been made, it has been found that the same objects as were sought by the institution in England have been sought by means which more strictly resemble those adopted in England, in proportion as the condition of the community resembles that of England in the complexity of its social relations, and the progress of its legal polity.

So general an adoption of analogous institutions amongst independent communities was, of course, not fortuitous, nor the mere result of imitation; and these institutions are everywhere of too distinct and recent an origin to be traceable to any of the primitive laws or customs of those people who have descended from one common race.

On the contrary, it was the development of the like evils in the progress of the civilization of each country which suggested the adoption of the like remedy. The evils, which were sufficient to induce nations to try a remedy so obviously fraught with great dangers both to the givers and to the receivers, and requiring sacrifices so immediate and so incapable of disguise, appear to have been at least as pressing elsewhere as in England. The description of these evils shows that they were and must be of universal prevalence, and that they have their origin in the constitution of mankind, and not in any such incidents as the dissolution of monasteries, or in any other local or temporary incident.

There never was a time or place in which there were not to be found men anxious to avoid labour, and yet to live in ease and enjoyment. There never was a time in which other men were not, from their sympathy, from their superstition, and from their fears, ready with their bounty to assist the necessitous, and liable to be imposed upon and intimidated, according as the beggar was crafty or bold. No community is so poor as not to suffer in some degree from the existence of a body of idle and worthless persons, subsisting profligately on the benevolence, the folly, or the fears of its members.

And as the condition of the people is found to improve, as progress is made in the arts and commodities of life, there is, of course, found a greater disparity in the condition of the people, and destitution more violently contrasted with opulence. Such a state of things, whilst it increases the means at the disposal of the benevolent and fortunate, increases the sympathy with the unfortunate, or those who appear to be so, and at the same time presents wealth in such masses as to serve as a temptation to those who may prefer to live by fraud or violence. Mendicancy and depredation, which are nearly impossible where a population is scattered, and its moveable wealth in small quantity, become easy in the contrary state of things.

It is accordingly found, in the progress of the civilization of every country, that a period arrives when beggary in its many forms, and with its whole train of consequences, appears in an alarming extent, usually even professed by large fraternities having some character of organization; sometimes connected by religious profession, like palmers, pilgrims, and various orders of mendicant friars, faquirs, dervishes; sometimes connected by supposed identity of race, as the people known throughout the continent of Europe, and largely in Asia, as Zingari, Gypseys, Bohemians: these, with the unfortunate and dissolute of all classes, find a means of living by practising various arts of amusement, and more frequently by operating on the superstitious credulity, and often on the fears, of the more wealthy and industrious part of the community. All accounts of such a state of things, wherever it may have prevailed, agree in showing that predatory habits almost invariably accompany, where occasion offers, the habit of mendicancy.

Great as were the evils obviously connected with the existence of such a mass of idlers, impostors, and depredators, there were not wanting motives to the other classes to perpetuate and increase the evil. Individual benevolence, even where accompanied by intelligence and prudence, although its objects may be immediately selected from the really unfortunate, would not withhold its indirect aid to this bad effect, its respectable example seducing many to imitate the act, without using the due precautions.

But a much greater share of the effect must always be attributed to the incautious benevolence of the great mass of those who have the power to give. It requires great knowledge and sagacity to distinguish the cases in which alms can be given without directly encouraging idleness, or

Origin and Object.

some worse vice; and to direct these qualities effectively to each application would, in the state of things described, require an amount of industry, and an expenditure of time, seldom or never possible. The ignorance and indolence, therefore, of the benevolent, afford the largest encouragements to the idle. Other influences are not wanting, especially ostentation and the love of popularity, which, where many live in idleness, never fail to create dependents and retainers to the full extent of the power or the will to maintain them. Superstition, too, has in all times enforced alms-giving as a virtue, and, operating upon the consciences of great criminals, has throughout the world created and endowed the largest and most magnificent of the so-called charities.

In the above description will be recognised a state of things partially exemplified, either in one set of its details or in another, in every country in Europe, more especially in those in which, like Spain, Naples, the Sardinian states, Ireland, and other countries, no public or well-controlled and systematic provision for the poor has been established.[1]

These observations will be well instanced in England during the progress of the institutions of which a description is about to be given.

CHAPTER I.

GENERAL OBJECTIONS TO PUBLIC RELIEF AND TO PRIVATE ALMS-GIVING.

The fact was adverted to in the beginning of this article, that the existing state of the poor-laws enables us to take a more dispassionate view of the abstract merits and defects of a system of public relief than was formerly possible.

Hitherto the question has been embarrassed by the consciousness of the evils which we were suffering, and of those towards which we were visibly making a rapid progress. On the other hand, the evils of general mendicancy, and the other painful and dangerous circumstances which are everywhere found to prevail where a public law of relief has not been established, are so little known in England, from whence our poor-laws have long excluded them, that little of the good really derived from our poor-laws was acknowledged, whilst the whole of their positive mischief was so apparent as to form almost alone the matter of every discussion of the merits of the system.

Alms-giving.

Before great accumulations of moveable wealth have taken place in any community, depredation to any large extent is scarcely possible, and mendicancy as a trade cannot be followed in such a community, especially where its population is widely scattered. Alms-giving, in the usual sense of the term, does not exist; but its place is often supplied by hospitality to the stranger and traveller, and by the readiness to share with friends or relatives the means of enjoyment which individuals may possess. But in countries where comparatively great accumulations of wealth have taken place, and where poor-laws have not been introduced, or where, as in Ireland, they have not taken root, alms-giving and begging are either avowedly permitted or connived at. And, for reasons hereafter to be shown, the alternative of a regulated system of *public relief*, or the practical permission, whether avowed or not, to solicit *private alms*, appears inevitable.

Objections to Public Relief, &c. Poor-laws.

It would be an evasion of the question to compare a well-devised system of poor-laws with a system in which alms-giving was to be substituted. It is necessary, in order to do full justice to the comparison, to assume a system of poor-laws fraught with all the evils known to be derivable from such a system, and administered with a degree of laxity not less than that of which we have had a practical experience. A system of public relief may be bad in principle, and yet judiciously administered; or it may be good in its principle, and ill administered. For the present purpose, a system shall be assumed, bad in its principle and bad in its administration.

Operation of a bad poor-law.

In this view, the law may give a claim to all persons not having means of independent subsistence, to be relieved, without subjecting the claimant to any harsh or disagreeable condition. Such a claim, though never in fact countenanced by the law, was practically allowed for above a quarter of a century in many parts of England. A law of this kind would obviously render all those who by their exertions could at the utmost earn but a bare subsistence, averse to industry, which in such a case would be a sacrifice of ease without any increased advantage. If present industry were rendered useless, so would thrift and forethought become a folly, an abandonment of present enjoyment without an object. Every present indulgence which the law allowed would wisely be enjoyed; good moral habits and bodily skill would have little merit if the law should place those with them and those without them in the enjoyment of the like benefits. What appears desirable for a man's advantage, it is a virtue in him to do also for his progeny. The paupers' children would be themselves paupers, and the law would present to them every inducement to beget other paupers, and no inducement to refrain. Such we have seen the English pauper, slothful, thoughtless but of his parish pay, sometimes living to see three generations of his progeny paupers, like to or worse than himself.[2]

But the idle pauper cannot be supported except from those funds which must otherwise employ and reward the industrious. Every pauper, for his support, consumes that which would maintain or nearly maintain an industrious labourer; with this difference, that the consumption of the pauper is never repaid, whilst the value of the labourer's consumption is always reproduced with a profit, which again affords the means of employing other industry. The pauper, therefore, is constantly drawing those above him into his own rank. The misfortune of those reluctantly becoming paupers produces a sympathy which extends to the voluntary pauper, and the unfortunate and the idle become less and less distinguishable.

If the law increases its bounty with the number of the paupers' offspring, all these evils are aggravated and accelerated. If the law, like the English bastardy law, renders the reward for having a bastard child greater than the allowance to a legitimate child, another source of immorality is opened, female virtue is at a disadvantage, and unchastity, becoming a source of profit, becomes respectable.[3]

If the law takes the yet more insidious course of providing relief to those who live partly by regular industry, the evils described are enormously increased. In this way the whole industrious population may be destroyed, almost without rendering the recipients conscious of their degradation. In this way the forethought of the industrious man becomes of as little value to him as it is to the pauper, and the whole of the restraints on population are destroyed in the great bulk of the people.

---

[1] For a very ample detail of the state of mendicancy and vagrancy of private and public charitable institutions, in the chief countries of Europe and in the United States, the reader is referred to the Appendix (F) of Foreign Communications made to the Poor-Law Commissioners, 1835, and especially to the interesting abstract of and comment upon these communications by Nassau W. Senior, Esq. entitled, "A Statement of the Provision for the Poor, and of the Condition of the Labouring Classes, in a considerable portion of America and Europe;" 8vo, Fellowes, 1835.

[2] See Extracts from evidence received by the Commissioners of Inquiry: "We have cases of three generations of paupers," p. 204. See at p. 218 an amusing instance of three generations of the same stock contemporaneously relieved, at the rate of L.100 per year, by a parish; see also pp. 220, 226, 358.

[3] See Extracts from the information received by the Commissioners of Inquiry into the Poor-Laws. A clergyman in Cumberland speaks thus of the practice of that county: "A very different description of women have of late years become the mothers of bastard

But relief to his workman is in fact for the moment relief to the master; the public undertaking a portion of the maintenance of the servant, saves to that extent the wages of the employer. The corruption of the system thus reaches the master as well as the labourer, and each is equally induced, by his immediate interest, to secure and continue to himself his portion of the benefit, unless we presume them to be more provident than the law itself.

That such bad principles might be involved in a poor-law, is undoubted; for although the English law never, either in letter or spirit, contained all these elements together, yet it at one period or another in succession contained them all, and a loose and in some measure a corrupt administration gave, for a long time, prevalence to all their influences together.

Evils of a bad administration of the poor-law.

This brings into view the evils of a bad administration of the law. Suppose its execution intrusted to officers who must, in a majority of cases, be necessarily ignorant of its complicate objects, being ignorant of the common rudiments of education;[1] and let such officers be in no way distinguished by their interests being made to accord with the interests of the community in a good administration; the obvious consequence must be such as we have seen in England, that the best portions of the law must be badly administered, whilst the bad parts, by such instruments, can scarcely be expected to have these evils softened by a good administration. But a certain consequence would be, that those whose interests were identical with the welfare of the community, would be reluctant to serve the office, which would thus be left to others who could best employ its provisions to their own advantage. Thus in England the overseer was generally found, even when zealous in the discharge of his duty, blindly giving effect to the most pernicious part of the system. When merely weak, without being corrupt, we find him a tool in the hands of those whose object it was to procure labour at a low price, at the expense of the other rate-payers, and at the peril of the gradual though certain deterioration of the labourer and his posterity. Such an overseer was also subject, as a matter of course, to the cajolery or intimidation of the pauper, to the seduction of popularity, readily to be got by the expenditure in mis-called charity of other people's contributions. But the natural operation of the system was to find or to make its officers corrupt, as it was natural that that class of men should be readiest to execrate the officer, whose circumstances best allowed them to avail themselves, for their own advantage, of the law. In England we found that the more pauperized the district, the more certainly was the overseer an employer of pauper labour, or a supplier to the paupers, on his private account, of the objects of their daily consumption, or the owner of the habitations in which they lived, and for which the parish guaranteed a certain and exorbitant rent.

Even these evils might be aggravated by parcelling the country out into districts too small to allow of the procuring of the necessary means even of an economical administration. In England, few parishes or townships were large enough to afford a workhouse or to contract for the supply of the articles of consumption for the poor. Many were so small, that the cost of purchasing small books of account was considered as an extravagance.

We have another important example of the way in which the administration could be carried to the extreme of badness; namely, by the provision of a control which could by its nature operate only to enforce an improvident administration, and which should have no authority to check it. England, again, affords us an example of such a device in the authority of the justices of the peace. The justice was enabled to enforce the giving of relief where the overseer from any motive had refused it; but the justice of the peace had no authority to interfere when the overseer was profligately allowing relief.

Effects of such a poor-law.

The effects of such a system, then, would inevitably be the same as we have witnessed in England. Such have been, perhaps, too indiscriminately attributed to poor-laws generally. These effects were, in a former article in this publication, very distinctly and ably described and elucidated. They were described, first, as a disturbance of the natural course of population, which they increased without reference to the means of support; and, indeed, in the inverse direction, inasmuch as every addition to the number of the non-productive or the partially productive paupers diminished the means of living of the other portions of the community. Secondly, as increasing the very pauperism which it was their object to relieve. Thirdly, as productive of improvidence in the poor, who saw no worse consequence of a dissolute and idle life, than an eventual reliance, in common with millions of their fellow-subjects, upon the parish for their support in sickness or old age, or in the visitation of those calamities against which it is the task of prudence to provide. A fourth effect, much dwelt upon, was the misapprehension caused by these institutions as to the real cause of poverty and distress, and the operation of this misapprehension in producing a discontented spirit in those who encourage the notion that they have a right to relief, but entertain no equally definite notion of their duty to provide for themselves. The fifth evil was the encouragement which the system, as administered, was found to give to every species of immorality: idleness in the day, encouraging depredation, poaching, and smuggling by night, facilitating the resort to the beer-shop again by day: particularly the law of bastardy was observed to be rapidly destroying the virtue of the females, and, by producing ill-assorted marriages, the whole of those domestic virtues, both of parents and children, which depend mainly on a happy home. And it was also remarked, that the law of settlement had a large effect in lowering the character of all who claimed a maintenance from the parish; it being notorious that the most steady, industrious, and moral workmen, upon whom the employer can place his surest reliance, are those who do not legally belong to the parish in which they are living.

Such is the description of an extensive system of poor-laws, framed on a bad principle, and badly administered; and such are their observed effects.

---

children. Formerly it was confined to the daughters of cottagers, and girls employed in farm-husbandry; but of late *very respectable farmers' daughters* have been in that situation, and have applied to have their offspring taken care of by the parish." (Captain Pringle's Report, p. 404.) The next extract is from the evidence of an overseer in the same county. "We at this time, in our parish, are supporting two bastard children, whose *mothers have landed property of their own*, and would not marry the fathers of their children." (*Ibid.*) "The daughters of some *farmers, and even landowners*, have bastard children. These farmers and landowners, and children with them, regularly kept back their poor-rate, to meet the parish allowance for their daughter's bastard." (*Ibid.*) "Captain Pringle states, that in the neighbourhood of Carlisle, it was not unusual for the daughters of small farmers, or statesmen as they are here called (men farming their own property), to have bastard children, and to come to the parish for allowance." (*Ibid.* p. 403.)

[1] See as to the illiterateness, general ignorance, and inefficiency of overseers, the volume of Extracts before cited, at the passages referred to in the index, under the title "Overseers."

But it does not thence follow, that a poor-law well devised and well administered should find no place in the polity of a nation.

There appear to be at least two resources besides that of adopting bad principles in such a law, or adopting a bad constitution of officers for its administration. The first resource is to exclude such an institution altogether.

lternative f alms-iving.

Some few countries taking their place by common estimation amongst civilized nations, have made no public provision for the poor. Ireland was practically, before the session of 1837–1838, without such a provision. England was in the same condition until the reign of Elizabeth. In all such countries rigorous enactments exist against mendicancy, but everywhere such enactments are defeated by the common co-operation of the whole people. It will be seen, that in England the most ferocious penal enactments were repeated, with every variation that ingenuity could devise, for the purpose of suppressing mendicancy and vagrancy; and yet at every stage of legislation it is avowed that the evil was still increasing. Ireland had, up to the time of Henry VIII. the English laws in this respect; and the sanguinary laws of Henry VIII. are still the laws of Ireland. Until this day, a criminal who evades conviction for some greater offence is occasionally transported under the vagrancy laws; in all other cases the public opinion revolts against the application of the penalty; and the law, though in the statute-book, is without effect.

It appears a preposterous expectation, that any people will generally sympathise or co-operate with the law which, whilst it leaves the unfortunate to perish, pretends to render mendicancy a crime. So common is the sentiment against such an attempt, that many systems of jurisprudence avowedly admit necessity, or the extreme danger of perishing for want, as a legal excuse for some offences, and as a palliation of any offence directly incited by the pressure of such necessity. There appears, therefore, no means of preventing mendicancy, but by a recognised provision of public relief.

Mendicancy is often expressly permitted by law; sometimes it is allowed to particular classes of persons, as discharged soldiers and sailors and their families, poor students, discharged prisoners, and such like. Sometimes a limit is assigned to begging, a given route on the way homewards, or a given district in which a party may have been born or may have become otherwise domiciled. Even in England, both these kinds of license and restriction have, till within these few years, formed part of our statute-law, and both species are still leading features in the law of Ireland. The effect of such restrictions has nearly everywhere been the same as in our own country, viz. to give authority to mendicancy, without in any way operating to diminish it.

endican-compar-with uperism.

Let us now examine the effects of mendicancy, whether permitted by the law or not; comparing it throughout with the operation of a bad system of poor-laws. In the *first* place, it, like pauperism, destroys industry, but the mendicant is wholly and entirely idle, with no one responsible to see him set to work, and, being for the most part unknown to those who relieve him, is under no necessity even to affect, like the pauper, a readiness to work. The mendicant's progeny is like himself in this respect, except that, being early bred to the parent's habits, industry becomes nearly impossible to them; whilst the occupation of both is such, that even on the supposition that an inclination to adopt a life of industry should be excited, few occupations could be found to which they would be fitted, and still fewer employers who would engage them. In respect of the influences upon *industry*, therefore, the individual mendicant is under worse influences than the individual pauper relieved by the *worst* system of poor-laws. So with respect to the general *morality* of the mendicant. The pauper is under some restraints, owing to his being settled amongst neighbours upon whose good opinion he is at least in some measure dependent; he must be known to the officers of his parish, and by this alone is kept in contact with and in fear of the law. The local sphere for the exercise of his vices is one of narrow limits. These restraints keep the pauper under considerable subjection, both to law and to opinion. But no such restraints operate upon the mendicant. No irregularity of conduct, no vice, can exclude him more from general society than his daily mode of life already does; even if, amongst his fellows, any vice should be recognised as sufficiently repulsive to exclude him from their companionship, their unsettled life renders it impossible that the reputation or the knowledge of his odious qualities could very closely attend him. Add to this absence of restraint the positive encouragement given by their more various and adventurous life, the zest with which its frauds and its darings are performed, and the glory with which they are recounted; these accompaniments have rendered the beggar's life popular, as the subject of romance, and occasionally as the object of imitation amongst even the better educated and more fortunate members of society. A pauper was never yet, as the beggar often is, the romantic hero of a ballad or a legend. Here, again, the influences on the individual mendicant are more pernicious than those on the pauper.

The same disadvantageous comparison exists when we consider the unlimited opportunities afforded by the mendicant's mode of life for every species of petty theft and depredation, habits which appear invariably to accompany that of vagrancy.

Extent of mendicancy.

In England we have a difficulty in conceiving the extent to which the habits of mendicancy may be carried on, and the varieties in its practice. It would be comparatively a small evil that a few mendicants should be found to be preeminently vicious characters; and this evil would bear no comparison with the evil of a pauperism spread as widely as that formerly in England. But some estimate may be formed of the extent to which mendicancy may be carried where there are no poor-laws, by a reference to the state of Ireland, in which it is represented that, in a population of eight millions, not less than 200,000 habitual mendicants and vagrants exist, and where this number is annually reinforced by the accession of the wives and families of those labourers who have left their homes in search of work elsewhere, and which are represented, in the evidence collected by the Commissioners of Poor-Laws Inquiry in Ireland, to exceed a million of persons.

The evil of mendicancy, therefore, may even bear a comparison in the extent and number of those practising it, with the evil of pauperism even under a bad poor-law.

Distributors of alms and of relief.

Now, let the operation upon the distributors in both cases be compared. No regular machinery is devised for the supply of the mendicant, but he is let loose upon the whole of society, to procure his living by every means by which the sympathies, the virtues, the follies, the weaknesses, or the vices of man may be attacked. Though much of the relief given to the mendicant is prompted by the benevolence of the giver, much also has its origin in sympathies falsely excited; in folly, and especially in the vanity and ostentation of him who dispenses the alms. Much, too, of the alms given to mendicants, in alms-giving countries, is given with the object of acquiring power over a disorderly and reckless class. In all countries, in times of commotion, we have seen this class unscrupulous instruments in the hands of those who, by their largesses, or by the exciting of expectations, had attached a large number of these classes. An example is seen in Spain, where the merit chiefly professed by the distributors of the alms of enormous charities is that of relieving the wants of armies of mendicants.

No instrument in the hands of ambitious and designing persons has ever been found more effective than that of retaining large classes of ready-formed mendicants, and of

Objections to Public Relief, &c.

bringing the poorer classes, under specious names, as near as possible to the condition of receivers of alms.

The effects upon the distributors has been equally to the disadvantage of the practice of alms-giving, inasmuch as the appointment of officers to administer the public fund has not been, and cannot be conceived to be, as pernicious as the innumerable institutions and fraternities of idle men brought together for the purpose chiefly of distributing alms. A portion of this operation may be seen and appreciated in the comparison between an ordinary overseer and the trustees who usually have distribution of private charities, the masses of which in England and Wales are shown by the Reports of the Commissioners of Charity to have been diverted from their proposed objects for the benefit of those who had the control in their hands.

Another advantage which a system of poor-laws has over alms-giving is this: Poor-laws are subject to the control of the legislature. Their evils, as discovered, may one by one be pruned away by the power which has created the whole institution; and they can also, at the will of the legislature, if such should appear to be an advisable course, be at any time totally abolished. Mendicancy, on the other hand, and alms-giving, are beyond the effective control of the law. Where once established by habit, no interference of the legislature can effectively modify them, no prohibition of the legislature can abrogate them. The sole corrective appears to be a retreat from private alms, by the adoption of a system of public relief as a means of discountenancing the mendicant's claim.

Thus far have been compared bad poor-laws with mendicancy; and it has been attempted to show that, even in this comparison, private alms-giving is exposed to disadvantages greater than those attached to a system of public relief. The comparison thus far with poor-laws has, as an abstract question, become unfair, because it seems possible, and recent experience appears to confirm the conclusion, that a poor-law may be so devised and so administered as to take away all plea for guilt founded upon absolute necessity; to diminish no man's present motives to labour, and bring up his offspring to industry; to offer the least possible inducements to improvidence, so far as improvidence is involved in neglecting to make accumulations against old age and other calamities. This appears to be rendered possible by the administration of such relief that those capable of working would reject it, as less desirable than independent industry in the time of their health and vigour, and less desirable than provisions secured by prudence for their old age.

CHAPTER II.

HISTORY OF ENGLISH POOR-LAWS TILL THE YEAR 1834.

The most authentic accounts, at least those which prove most incontestibly the prevalence of the habits of mendicancy and vagrancy in England, and give the best evidence of the extent to which their evils were recognised, may be found in the expressions of our early statutes.

It will not be possible to give a detailed description, either of the contents of the series of our statutes, or of their effects. The number of statutes passed for the suppression of vagrancy, mendicancy, and idleness, and for the relief of the poor, amount at the least to a hundred and eighty-seven; those now in force, commencing with the statute 43 Elizabeth, and including only the modifications of that law, amount to a hundred and eighteen, and contain matter of itself about equal to four average volumes of the statutes at large. None, therefore, but the most salient points in the legislation of the last four centuries and a half will be adverted to in the following summary of the progress of legislation upon these subjects.

History of English Poor-Laws.

We first find indications of a general relaxation of the industry of our population in the reign of Richard II. Civil discord had unquestionably its effect in producing the result; but a change in the habits of the population had been produced by the increase of commerce and of communication with other countries, and a large accession had at this time been made to the disposable wealth of the community. The large system of vagabondage, sanctified by the name of pilgrimage, of which the expeditions known as the Crusades were the most salient instance, had begotten a spirit of restlessness and idleness in Europe, infecting even our insular population. It was not so much the habit of beggary, as the desire of change and restlessness of life, that the statute of the 12th Richard II. chap. 7, passed in the year 1388, was intended to repress. This statute, though entirely directed against habits characterized in that day as vagabondage, scarcely recognises beggary as an habitual pursuit. Its main provisions are confined to the object of restraining labourers from changing their abodes. It prohibits any labourer from departing from the hundred, rape, wapentake, city, or borough, where he is dwelling, without a testimonial showing reasonable cause for his going, to be issued under the authority of the justices of peace. Any labourer found wandering without such letter is to be put in the stocks till he find surety to return to the town from whence he came. So far are its enactments from affording any evidence that able-bodied persons of either sex exercised by choice to any large extent the trade of mendicancy, that the only other class besides labourers which it recognises are the impotent. As to impotent persons, it provides that they are to remain in the towns in which they be dwelling at the time of the act; or if the inhabitants are unable or unwilling to support them, they are to withdraw to other towns within the hundred, rape, or wapentake, or to the towns where they were born, and there abide during their lives.

Restraint of vagrancy,

From the earliest periods, but from this time especially, begging was an offence; yet the chief enactments of the two succeeding centuries are rather confined to the object of restraining the movements of labourers than to the restraining of able-bodied beggars. The provisions of the 11th Henry VII. chap. 2, however, require beggars not able to work to go to the hundred where last they dwelt, or were best known, or born, without begging out of the hundred. The 19th Henry VII. chap. 12, passed eight years afterwards (in 1504), requires them to go to the town, city, or hundred where they were born, or to the place where they last abode for the space of three years, without begging out of the said city, town, hundred, or place.

of begging.

The legislation affecting the classes of poor least able to provide for themselves, had thus far been entirely restrictive, and contained that element of the poor-laws by which they are connected with police, almost to as great an extent as is to be found in our most recent institutions. They also indirectly contain a complete settlement law; for, by confining the labourers, but especially the impotent poor and beggars, to the places in which they dwelt at the time of the act being passed, or in which they had been born, or to the places of their last abode, they directly settled such persons on the places thus defined, and rendered the districts chargeable with the burden, at least to the extent to which the endowments of the church and the benevolence of individuals could be applied to the purpose. At length, especially after all the revenues of the church were diverted from the purpose of maintaining the poor, legislation becomes of a severe penal character, and is more immediately directed against those who practise mendicancy as a trade, viz. "able-bodied, sturdy, and valiant beggars." At the same time, the distinction becomes more apparent

Settlement law.

between the impotent poor and those whom the legislature evidently regarded as voluntary poor, and whom the law now subjects to heavy and even sanguinary penalties. The 22d Henry VII. chap. 12, passed in the year 1531, directs the justices to assign to the impotent poor a limit within which they are to beg. An impotent person begging out of his limit is to be imprisoned for two days and nights in the stocks, fed on bread and water, and then sworn to return to the place in which he was authorized to beg. An able-bodied beggar is to be whipped, and sworn to return to the place where he was born, or last dwelt for the space of three years, and there put himself to labour.

mpul- y relief.

Thus far restrictions upon vagrancy, whether originating in misfortune or idleness, or more serious vice, had proved unavailable. The evil had not been repressed; it had evidently increased, and at length drove the legislature to the adoption, not only of severer penalties, according to the old policy, but of a new expedient.

With imperfect machinery for giving effect to its intentions, without security that where its intention was carried into effect evils greater than those against which it was intended to provide might not arise, a system was now created which, in all its policy, is identical with that which now exists in England, and is about to be introduced into Ireland. The means employed, and not the policy itself, alone distinguish the legislation of the two periods. In the first place, beggary and vagrancy are still to be repressed, but no one is to be driven, by absolute destitution, to an infraction of the law; all excuse is to be taken away from the beggar. In the next place, the sympathy of the community with the law is to be secured by a provision at the public expense against the evil consequences of individual destitution. In the last place, the compulsory provision thus made by the community is to be protected by compelling those capable of exertion, and seeking to avail themselves of it, to accept it subject to the condition of working for the maintenance thus secured to them; a condition obviously intended to be as hard or harder than that upon which the independent man obtains his own support, and rendering the alternative of independent industry preferable to that of dependence on the public charity.[1]

The 27th Henry VIII. chap. 25, passed in the year 1536, recites the act last mentioned, and adds, that no provision is made for the support of the impotent, nor for the setting and keeping in work of valiant beggars; and then enacts, that the land-officers of every city, shire, town, and parish, to which such poor creatures or sturdy vagabonds shall repair, in obedience to that act, shall most charitably receive the same, and shall keep the same poor people by way of voluntary and charitable alms, within the respective cities, shires, towns, hundreds, hamlets, and parishes, by their discretion, so that none of them, of very necessity, shall be compelled to beg openly, and shall compel the said sturdy vagabonds and valiant beggars to be kept to continual labour, in such wise as they may get their own living by the continual labour of their own hands, on pain that every parish making default shall forfeit twenty shillings a month. Alms-giving otherwise than to these common boxes, or common gatherings, or to fellow-parishioners, or prisoners, is prohibited on forfeiture of ten times the amount given. A sturdy beggar is to be whipped the first time, his right ear cropped the second time; and if he again offend, he is to be sent to the next jail till the quarter-sessions, and there to be indicted for wandering, loitering, and idleness; and if convicted, *shall suffer execution of death as a felon*, and an enemy of the commonwealth.

As far as the policy of the succeeding legislation is concerned, its intention appears to be fully expressed by the terms of this statute. In all the succeeding period, we find a very large variety of means adopted for the purpose still of giving effect to the same policy; sometimes an increase of severity, even beyond the rigour of this statute, against the beggar and vagrant; sometimes an improved machinery for succouring the impotent, especially for the assessment and levying of the funds, and for producing an effective responsibility in the officers charged with this duty; and eventually a more comprehensive system devised for effectuating the whole of the objects clearly contemplated by the statute of Henry, without the adoption of any other than those objects, but intended merely to prevent the evils resulting from the defective means and instruments previously employed for their attainment.

Accordingly we find in the statutes of the reign of Edward V. "the foolish pity and mercy of them which should have seen to the execution of the goodly laws before enacted, and the perverse nature and long-accustomed idleness of persons long given to loitering," inveighed against in the usual declamatory manner of preambles of that period; but we find indications of the growth of a conviction that the excessive penalties of the previous legislation had defeated the operation of the law. The enactments against vagrancy are therefore rendered somewhat milder; an able-bodied poor person who does not apply himself to some honest labour, or offer to serve, though only for meat and drink, if nothing more is to be obtained, shall be taken for a vagabond, branded on the shoulder with the letter V, and adjudged a slave for two years to any person who shall demand him, to be fed on bread and water and refuse meat, and caused to work by beating and chaining, or otherwise. If he run away within that period, he is to be branded on the cheek with the letter S, and *adjudged a slave for life*; if he run away again, he is to suffer *death as a felon*. If no one demand such loiterer, the place where he is born is to keep him as a slave, and is to see him set to work; and if it fail in this, it is to be mulcted in a penalty, a city forfeiting five pounds, a borough forty shillings.

Removals.

By this statute the old settlement law had ingrafted on it a law of removal. The taking surety of the impotent poor, that they would repair to the places where they were born, or had dwelt for the last three years, had been found ineffectual; the officers were therefore directed to convey the impotent poor on horseback, in cart, chariot, or otherwise, to the next constable, and so from constable to constable, till they be brought to the place where they were born, or most conversant for the space of three years, there to be kept and nourished of alms.

Gradual improvements were introduced in the detail by several successive statutes. The 3d and 4th Edward VI. provides for the keeping of a book in every city, corporate town, and parish, containing the names of householders, and of the impotent poor. It makes some approach to a special organization of officers for the objects. The minister and churchwardens are to appoint collectors of alms; the alms, however, are voluntary, except to the extent to which they can be enforced by the exhortation of the minister and bishop; it being provided, that if any one able to further this charitable work do obstinately and frowardly refuse to give, or do discourage others, the minister and church-

---

[1] With regard to the erroneous impression until recently prevalent in England, that poor-laws were institutions peculiar to this country, it is important to observe, that the system of law for repression of mendicancy and relief of the poor here described, was a direct and palpable imitation of a continental institution. Six years before the enactment of the 27th Henry VIII. (that is, in the year 1530), the magistrates of Ypres, in Belgium, enacted a set of regulations, which, as stated by Mr Hallam, manifestly form the model which was followed a few years afterwards by the legislature of this country. The regulations in question appear to have been adopted in the adjacent provinces of the Netherlands, under the sanction of an edict of Charles V. See a paper by Mr Hallam in the first volume of the Transactions of the Statistical Society.

History of English Poor-Laws.

wardens are to exhort him gently. If he will not be so persuaded, the bishop is to send for him to induce and persuade him by charitable ways and means, and so, according to his discretion, to take order for the reformation thereof. These provisions being made, beggary is still prohibited, upon the pains limited in the previous statutes.

Compulsory tax.

As might be expected, the gentle askings of the collectors, and the exhortations of the minister, the charitable ways and means of the bishop, appear to have been without effect in persuading the parishioners to intrust to the collectors the distribution of their alms. We find, therefore, twelve years afterwards (5th Elizabeth, chap. 3, passed in 1563), an attempt made to give additional effect to these provisions, by enabling the bishop to bind any person to appear at the next sessions, if his froward and wilful mind should obstinately refuse to give weekly relief to the poor according to his ability. Here the justices are to come in to the aid of the bishop, and are charitably and gently to persuade and move the said obstinate person to extend his charity. If he will not be persuaded, the justices with the churchwardens may tax the obstinate person according to their discretion; and on his refusal to pay, the justices, on the complaint of the churchwardens, are to commit him to jail until he does pay the sum taxed, and arrears. Thus was created a compulsory tax, though at first only as an alternative where voluntary contributions were refused.

The important statute, 14th Elizabeth, represents in its recitals, that "all parts of this realm of England and Wales be presently with rogues, vagabonds, and sturdy beggars exceedingly pestered, by means whereof daily happeneth in the same realm horrible murders, thefts, and other great outrage." The sense of these evils seems to have dictated a resort to a new variety of punishments; all persons defined in the act as rogues and vagabonds, or sturdy beggars, are for the first offence to be grievously whipped and burned to the gristle of the right ear with a hot iron, of the compass of an inch about; for the second, they are to be deemed felons; for the third, to suffer death as felons, without benefit of clergy. But now chiefly is to be observed the improvements in assessing the burthen; the justices having power to settle the poor for their abidings, and to set down what portion the weekly charge towards the relief and sustentation of the poor people would amount unto, and that done, shall by their good discretions tax and assess all the inhabitants dwelling within the divisions limited for the settling of the poor.

License to beg.

This statute contained, like some of its predecessors, an enactment giving a limited license for begging, provided that the poor people ask relief of victualling only in the same parish where they do dwell, so the same be at the time and in the manner directed by the churchwardens and overseers of the poor. This license has been extended, modified, and restrained, but still kept in existence, especially in the case of discharged soldiers and prisoners, up to recent times.

43 Eliz. cap. 2.

So far we have seen the gradual accumulation of all the elements contained in the poor-laws up to the time of the last amendment in the system made in the reign of the late King William IV. The statute which permanently fixed all these elements in one system was passed in the last year of the reign of Elizabeth, the celebrated statute the 43d Elizabeth, chap. 2. In this statute we find extreme severity abandoned, and its place supplied with a reasonable test of destitution of such as may be presumed to be voluntary beggars or idlers. The able-bodied, married or unmarried, are to be set to work; children may be apprenticed; only the "lame, impotent, old, blind, and such others among them, being poor and not able to work," are to have "necessary relief," without being set to work. For the latter class of poor, habitations may be provided at the expense of the parish, on the waste or common; and for the support of these, but not of any who are able to work, natural relations, that is, father, mother, grandfather, grandmother, and children, may be compelled to contribute.

The voluntary contribution, and the co-operation of the minister and bishop, are abandoned. A tax upon the inhabitants, and upon the occupiers of property, strictly defined, and upon the parson or vicar, is directed to be levied in every parish; effectual means are given for the assessment, collection, and levy of the tax; for appeal for remedy against its unjust assessment; for the contribution of adjoining parishes and hundreds, where the means of the single parish failed; above all, a special authority is created for giving effect to the provisions of the law. Overseers, not less than two, nor more than four, are to be appointed in every parish yearly, in Easter week, to act with the churchwardens, subject to the orders of the justices, and liable to penalties for neglect of their office.

Such was the system in operation for above two centuries and a quarter, from 1601 to 1834, without material modification: its whole provisions were extended in the reign of Charles II. to town-lands; the law of settlement was also extended and refined, in the same and subsequent reigns; and the provision for setting the able-bodied to work was rendered more effectual by the 9th George I. chap. 7, which enabled every parish to provide a workhouse, or, if too small or too poor, to combine with others for the purpose of maintaining a workhouse, and which rendered the offer of relief in a workhouse a sufficient bar to the claim to any other relief.

Diminutio of vagrancy.

These statutes, aided by all those other causes which operated upon the morals and the general prosperity of the people, had produced the effect intended by their authors; and whatever may have been the portion attributable to any of the several causes in operation, the result unquestionably was, that vagabondage and idleness were found in the last half of the last century to prevail in England to a less extent than in any of the larger states of Europe, with the single exception of Holland. As the extremity of the evil had formerly produced severity in the law, so the disappearance of the evil produced a disastrous relaxation in the restrictions of which the experience and prudence of the previous times had discovered the necessity.

Relaxatio of the law

About the middle of the last century, there began to be indicated in the acts of the legislature a growing opinion, that the severity of the tests applied to the recipients of public charity required to be diminished. In the 7th year of the reign of George III., guardians were especially appointed in the city of London, the city of Westminster, the bills of mortality, the liberties of the Tower, not with any administrative or executive powers, but "to guard against the dangerous consequences which may arise from the false parsimony, negligence, inadvertency, or the annual change of parish officers." These guardians were to protect the poor children of the metropolitan districts to which the act applied, by visiting the places in which they were kept, reporting on their condition, and calling on the assistance of the magistracy where it might seem necessary.

Throughout the whole of the reign of George III. the example thus set was followed by constantly succeeding and increasing relaxations of the rigour of the old law; some of the most conspicuous instances of which are to be found in Gilbert's act, passed in the twenty-second year of that reign, 1782, which, instead of rendering the workhouse a means of testing voluntary pauperism, by employing the able-bodied, thereby deterring them from habits of pauperism, by rendering their state less eligible than one of independence, reverses this principle entirely. It confines the use of the workhouse to that of a mere receptacle for the aged, impotent, and infant poor; and provides, that the able-bodied shall not be required to enter it; and proceeds to the absurd extent in favour of the able-bodied pauper, of com-

History of English Poor-Laws.

pelling the guardians appointed under the act to find work near their own houses, for all applicants able and professing to be willing to work, but unable to get employment; and to make up any supposed deficiency of wages out of the poor-rates.

The evils of able-bodied pauperism were now proceeding with alarming rapidity. The consummation of the false policy of the legislature during this reign was attained in East's act, 55 Geo. III. chap. 137 (passed 1815). It consists of a complete abrogation of almost all the salutary portions of the 9th Geo. I. chap. 7. The relief was no longer required to be received in the workhouse, it was to be *paid* to any poor person or persons at his or her or their home or homes, house or houses. Justices were empowered to order this relief for any time they might be pleased to define, not exceeding three months; and two justices might make subsequent orders for relief for a period not exceeding six months. The preambles and recitals in this statute consist, as might have been anticipated from the previous course of legislation, of descriptions of the grossest disorders on the part of those maintained by the public charity.

The insolence and general demoralization of the pauper, the most alarming deterioration in the industry of the labouring classes, especially the agricultural labourers of the south of England, the unscrupulous interference of the employers with the wages and the mode of remuneration of the employed, were abundantly shown by the committees of both houses of parliament, appointed to inquire into the progress of the poor-laws, especially by that appointed on the motion of Mr Sturges Bourne (in 1817), and upon the report of which the act known as Sturges Bourne's act, passed in the last year but one of this reign (the 59th Geo. III. c. 12), was founded. This act does not entirely abandon the views which dictated the dangerous provisions of East's act. Generally, however, it was a salutary measure, providing for the election of bodies of persons called select vestries, who were to supersede the overseers, and, in some measure, the justices, more effectually to avoid the evils consequent upon the administration being intrusted to annual and unpaid officers. It made provision also for the performance of the overseers' duties, by paid and permanent assistant overseers.

From the end of George III.'s reign to the year 1834, though legislative changes were not unfrequent, they were confined to matters of detail, involving neither the abandonment nor the adoption of any important principle.

CHAPTER III.

EFFECTS OF POOR-LAWS IN ENGLAND.

Commission of Inquiry.

fects of evious gislation.

In the course of the foregoing description of some of the principal statutes, the useful or injurious principles involved in them have been shortly referred to; the effects operated by the working out of those principles have been less remarked upon. In the main, the *good effects* had consisted in reclaiming from a vagrant and profligate course of life a large proportion of the population. The settlement laws especially had been instrumental in this; for we find that the creation of the claim to relief from the parish funds had so far attracted the idle and dissolute from the practice of common begging, that, in the reign of Charles II., after a period of great commotions, when many disbanded soldiers and sailors, and others, who, in a period of turmoil, are either forced upon or voluntarily resort to an unsettled life, had much swelled the mass of those who in previous times would have been found in the ranks of sturdy and valiant beggars, the same order of people were now found to be systematic though rapacious paupers, making the parish fund the means of levying their contributions on society.

neficial fects.

Operation.

We find in a statute of Charles II. in the second year of the Restoration (13 and 14 Car. II. cap. 12), a multifarious law of settlement created, upon reasons thus expressed in the recital: "Whereas, by reason of some defects in the law, poor people are not restrained from going from one parish to another, and therefore *do endeavour to settle themselves in those parishes where there is the best stock*, the largest commons or wastes to build cottages, and the most woods for them to burn and destroy; and when they have consumed it, then to another parish; and at last become rogues and vagabonds, to the great discouragement of parishioners to provide stocks, where it is liable to be devoured by strangers." From this period the whole of the efforts of the legislation are incessantly made to prevent the too easy settling of the poor upon the parish; but they all equally prove that settled pauperism had more and more taken the place of vagrant mendicancy.

If to the poor-laws can be attributed this good effect, they must also necessarily have the credit of preventing that train of evils which follows upon the existence of a large mass of mendicants and vagrants in any community. The corruption, the demoralization, the inevitable bodily misery, to the mendicant himself, his connections, and his offspring; the extortion, depredation, and the more violent crime which such a class have almost unlimited opportunity and frequent temptation to commit; next the deterioration in the feelings and habits of those whom circumstances may bring in contact with them; the refuge which they afford to all who are inclined or tempted to fall off from the more steady and respectable occupations of life, many of whom are even tempted by the mere spirit of adventure to become recruits; add to these the alarm and practical annoyance, which renders the industry and morality of all other classes less a security for enjoyment; and we have some idea of the train of evils the prevention of which was cut off when vagrancy on the great scale was at length, in England, successfully suppressed, though to be replaced in a great measure by voluntary and resolute pauperism.

Injurious effects.

The *bad effects*, as they arose in detail, usually led to the successive modifications which we find the law in its progress undergoing from time to time. Many of the evils temporarily and partially felt might even now be described with advantage, and as warnings to future legislators; but generally their interest would at present be greater to the historian and antiquary than in a practical point of view. At no period had these laws attained such an influence on the interests of the community of England and Wales, as about the years 1831 and 1832, when the effects of the whole system had reached a greater height than had ever yet been attained.

In these years many of the anticipations of those who had seen the evil tendency of the poor-laws, and had prophesied that the results of the system must be disastrous, were realized in such a way as to produce a conviction in the most supine, that either a remedy must be applied, or a wide-spread ruin be submitted to. In an article in this work, written in the year 1823, by one of the most humane and enlightened men who had ever given their attention to the subject, it was shown that a crisis was impending, and could not be far removed; that, as the law then stood, the poor-rates were increasing in the same ratio in which the prudence and forethought of the receivers of relief were being destroyed. It was shown, that "whenever the charge upon the land in support of those who do not add enough to the annual produce of the country to support themselves is so great that the land can be no longer cultivated with profit, then of course it will be thrown up." In 1832 was seen the phenomenon of whole parishes of fertile land being abandoned, "the landlords giving up their rents, the farmers their tenancy, the clergyman his glebe and the tithes." We find the paupers assembled and refusing to accept of the offer

Operation.

of the whole land of the parish, avowing that "they liked the present system better."[1]

In the article referred to, it had been shown that the system then in operation was fraught with the danger of discontented turbulence. "Every one is brought up with the belief that the state is bound to provide him with employment and support. When, therefore, the employment assigned him is such as he does not approve, and the recompense awarded him falls below his expectations (and when the employment is a loss to the public, the recompense must often be below even reasonable expectations), he becomes an irritated and uneasy subject; and, unless he is restrained by the fear of detection, or by the better influence of moral principles, he vents his spleen by any mischief that is in his power, and the burning of stackyards, or the destruction of machinery, results from an unsatisfactory interview with the overseer, or an ineffectual appeal to the bench of magistrates."

In the winter of 1831–1832 we find the practical exemplification of these remarks. In a period of great general prosperity, we find that portion of England in which the poor-laws had had their greatest operation, and in which by much the largest expenditure of poor-rates had been made, the scene of daily riot and nightly incendiarism; and we discover a state of things which, in the sober language of statistics, is thus described: "Of ninety-three parishes in four ill-administered counties, the population is 113,147, and the expenditure L.81,978, or fourteen and fivepence per head; and of eighty parishes in three well-administered counties, the population is 105,728, and the expenditure L.30,820, or five and ninepence per head; and those counties in which the expenditure is large are those in which the industry and skill of the labourers are passing away, the connection between the master and servant has become precarious, the unmarried are defrauded of their fair earnings, and riots and incendiarism have prevailed. The three counties in which it is comparatively small are those in which scarcely any instance of fire or tumult appears to have occurred; in which mutual attachment exists between the workman and his employer; in which wages depend not on marriage, but on ability, and the diligence and skill of the labourers are unimpaired or increased."

The danger had become too real to be neglected if a remedy could be found; but parliamentary inquiries, both in the upper and lower house, had repeatedly taken place comparatively without result, the largest effect produced by any committee of either house being that of the committee appointed in 1817, which in the year 1819 produced Sturges Bourne's act; an act, as events proved, almost wholly unproductive of effect in checking the course of pauperism.

An effort of another kind was now felt to be necessary, and was accordingly made. A Commission of Inquiry was appointed, consisting of individuals remarkable alike for their interest in the subject and their knowledge of its principles and details; its powers, though only those of ordinary commissioners of inquiry, far exceeding, for useful purposes, those of a parliamentary committee. Its labours were continued incessantly for two years, uninterrupted by the vacation or recess. Nor were these confined alone to the examination of witnesses summoned from different parts of the country. The commission were enabled to examine the locality itself, the documentary evidence, the living witnesses, and the actual operation of the system on the spot, and this by the members of their own body, as well as by assistant-commissioners appointed to visit and examine all parts of the country, some of whom extended their inquiries into Scotland, France, Flanders, and Guernsey, whilst

Operation.

they also collected a vast mass of interesting evidence from our ambassadors and diplomatic agents in different countries of Europe and America.

The result was a scrutinizing and minute inquiry; which was followed by the suggestion of amendments in the law, the practical deductions from the experience, yet so systematic, that their operation could be calculated almost with certainty, and which were, therefore, proportionally to be relied upon. As the success in inquiring had been great, so was the confidence of the legislature readily given; and the most important statute upon the subject passed since the statute of Elizabeth was carried through both houses by large and confident majorities.

A description of the evils found in operation at the time of the inquiry, of the remedies proposed for those evils, and of the enactments actually adopted, will afford the most complete and consistent view of the present system of English poor-laws. The statement of the operation of the previous law, and of the remedies proposed, will be condensed from the Report of the Commissioners of Inquiry; that of the enactments passed, from the Act for the Amendment and better Administration of the Laws relating to the Poor in England and Wales, being 4 and 5 William IV. cap. 76.

The poor entitled to relief consist, *first*, of those who are impotent through old age or bodily infirmity, through infancy, through accident, or through mental infirmity; and, *secondly*, of the able-bodied poor.

I.—RELIEF OF THE ABLE-BODIED.

It was in the relief of the able-bodied that the greatest pecuniary expenditure, and, above all, that the greatest moral evils, were incurred. The relief granted was in a great measure unconditional; in many districts it had superseded the necessity of practising even the thrift and husbandry necessary in expending the funds placed at the pauper's disposal.

The great source of abuse was found to be the out-door relief afforded to the able-bodied on their own account, or on that of their families. This was given either in kind or in money.

1. *Out-Door Relief of the Able-Bodied in Kind.*

The out-door relief of the able-bodied, when given in kind, was found to consist rarely of food, rather less unfrequently of fuel, and still less unfrequently of clothes, particularly shoes; but its most usual form was that of relieving the applicants, either wholly or partially, from the expense of obtaining house-room. This last mode of relief was extensively prevalent, and productive of important consequences, both direct and indirect.

Partial relief from the expense of obtaining house-room was given, or professed to be given, whenever the occupant of a cottage or an apartment was exempted on the ground of poverty from the payment of rates. In a great number of cases the labourer, if a parishioner, was not only exempted from rates, but his rent was paid out of the parish funds.

2. *Out-Door Relief of the Able-Bodied in Money.*

The out-door relief afforded in money to the able-bodied on their own account or on that of their families was found to be still more prevalent. This was generally effected by one or other of the five following expedients, which may be concisely designated as, first, relief without labour; secondly, the allowance system; thirdly, the roundsman system; fourthly, parish employment; and, fifthly, the labour-rate system.

Relief without Labour.—By the parish giving to those who were or professed to be without employment, a daily or a weekly sum, without requiring from the applicant any labour.

---

[1] See, as to the parish of Cholesbury in Berkshire, the Report from his Majesty's Commissioners for Inquiring into the Administration and Practical Operation of the Poor-Laws, 8vo Fellowes, 1834. See also instances in Warwickshire, in Mr Villiers's Report, in Appendix (A).

Sometimes relief, to an amount insufficient for a complete subsistence, was afforded, without imposing any further condition than that the applicant should shift, as it was called, for himself, and give the parish no further trouble. In a still greater number of instances the relief was found to have been given on the plea that the applicant had not been able to obtain work, that he had lost a day or a longer period, and was entitled, therefore, to receive from the unlimited resources of the parish what he had not been able to obtain from a private employer.

Allowance.—By the parish allowing to labourers who were employed by individuals, *relief in aid of wages.*

In some places allowance was found to have been given only occasionally, or to meet occasional wants; to buy, for instance, a coat or a pair of shoes, or to pay the rent of a cottage or an apartment. In others, it was considered that a weekly sum, or more frequently the value of a certain quantity of flour or bread, was to be received by each member of a family.

The latter practice was found to have been sometimes matured into a system, forming the law of a whole district, sanctioned and enforced by the magistrates, and promulgated in the form of local statutes.[1] The allowance fixed by these scales was usually called *bread-money.* Of this kind of relief it was observed, that

"No attention was paid to either the character of the applicant or the causes of his distress. In fact, he was considered as entitled to it without pleading any distress.

"The *bread-money* was hardly looked upon by the labourers in the light of parish relief. They considered it as much their right as the wages they received from their employers, and, in their own minds, made a wide distinction between 'taking their *bread-money*' and 'going on the parish.'"

It was further to be observed, that even in those parishes in which the amount of allowance was supposed to depend upon that of the applicant's earnings, the inquiry as to the amount of those earnings was never carried back further than the current or the previous week or fortnight. The consequence was, that many of those who at particular periods of the year received wages far exceeding the average amount of the earnings of the most industrious labourer, received also large allowances from the parish.[2]

Again, there were other parishes in which no sort of inquiry whatever was made respecting earnings; but the birth of a child endowed the parent with an allowance, whatever might have been his previous income.[3] It was to be observed, also, that under the *scale system* a child was very soon considered as an independent claimant for relief, and entitled to it, though residing with his parents, and though they might have been at full work on high wages.[4]

The Roundsman System.—By the parish paying the occupiers of property to employ the applicants for relief at a rate of wages fixed by the parish, and depending not on the services but on the wants of the applicants, the employer being repaid out of the poor-rate all that he had advanced in wages beyond a certain sum. This was the house-row, or roundsman, or billet, or ticket, or stem, system.

According to this plan, the parish in general made some agreement with a farmer to sell to him the labour of one or more paupers at a certain price, and paid to the pauper out of the parish funds the difference between that price and the allowance which the scale, according to the price of bread and the number of his family, awarded to him. It had received the name of the billet or ticket system, from a ticket signed by the overseer, which the pauper in general carried to the farmer as a warrant for his being employed, and took back to the overseer, signed by the farmer, as a proof that he had fulfilled the conditions of relief. In other cases the parish contracted with some individual to have some work performed for him by the paupers at a given price, the parish paying the paupers. In many places the roundsman system was effected by means of an auction.[5]

Parish Employment.—By the parish employing and paying the applicants for relief.

The 43d Elizabeth does not authorize relief to be afforded to any but the impotent, except in return for work. And

---

[1] "*Town of Cambridge.*—The churchwardens and overseers of the poor are requested to regulate the incomes of such persons as may apply to them for relief or employment, according to the price of fine bread, namely,

"A single woman, the price of...3½ quartern loaves per week.
"A single man........................4½ ... ditto.
"A man and his wife................8 ... ditto.
"A man and his wife and one child...9½ quartern loaves per week.
"Ditto ditto and two children......11 ... ditto.
"Ditto ditto and three ditto.........13 ... ditto.

"Man, wife, four children and upwards, at the price of 2½ quartern loaves per head per week.

"It will be necessary to add to the above income in all cases of sickness or other kind of distress, and particularly of such persons or families who deserve encouragement by their good behaviour, whom parish-officers should mark both by commendation and reward.

"By order of the magistrates assembled at the town-hall, Cambridge,—A CHEVELL, clerk to the magistrates.—*Nov.* 27, 1829." (Report, p. 22.)

[2] Mr Bishop found a parish in the Bedford Level, in which a recently drained tract of fertile land requires more labour than the settled inhabitants can provide, and the average yearly earnings of a labourer's family are from L.60 to L.70; but during a frost, and generally from November to March, almost every labourer comes on the parish. When they commented on these facts in their conversation with a resident magistrate, his answer was, "Why, what are we to do? they spend it all, and then come and say they are starving; and you must relieve them." "In our vestry," says Mr Russell, "which meets every Monday, the calculation is confined to the earnings of the past fortnight. No further retrospect is ever taken either for or against the claimant. In some parishes I believe the account is settled once a week instead of once a fortnight." Sometimes the inquiry does not go back even to the beginning of the week at the end of which the claim is made. (*Ibid.* p. 29.)

[3] In the northern division of Devonshire, says Mr Villiers, "The practice of granting allowance for children is so general and confirmed, that the pauper is in the habit of giving formal notice to the overseer of the pregnancy of his wife. Should the overseer refuse the application for the fixed sum allowed for the second, third, or fourth child, the magistrates' single inquiry, on his appearance before them under a summons, would have been as to the custom of the parish or the hundred. 'At what number does allowance begin with you?' was the common mode of putting the question, as I was repeatedly assured by overseers. The previous or present earnings of the pauper, or of any of his family, were never mentioned." (*Ibid.* p. 31.)

[4] At Friston, Suffolk, Mr Stuart states that "a child is entitled to relief at the rate of three shillings a week on his own account from the age of fourteen." "At Bottisham, Cambridge," says Mr Power, "a boy of sixteen receives two shillings and sixpence for the week; he lives at home with his father; the family consists of his father, mother, brother, and himself. Seventeen is the age at which a young man is considered entitled to separate relief as an unemployed labourer; his pay then is three shillings and sixpence. The allowance to our single young men out of employ used to be two shillings and tenpence; according to scale, four quartern loaves, present price eightpence-halfpenny. Last November they came to the sessions in a body to complain of the insufficiency, and it was then raised to three shillings and sixpence. This sum they receive when above a certain age, although residing with their families." (*Ibid.* p. 31.)

[5] Mr Richardson states that, "in Sulgrave, Northamptonshire, the old and infirm are sold at the monthly meeting to the best bidder, at prices varying, according to the time of the year, from one shilling and sixpence a week to three shillings; that at Yardley-Hastings, all the unemployed men are put up to sale weekly; and that the clergyman of the parish told him that he had seen ten men the last week knocked down to one of the farmers for five shillings, and that there were at that time about seventy men let out in this manner out of a body of 170." (*Ibid.* p. 28.)

Operation.

much as this part of the statute had been neglected, its validity was still recognised by the judges. In the King *v.* Collett, 2, Barnewell and Cresswell, 324, Lord Tenterden decided it to be the duty of overseers to provide work, if possible, before they afforded relief. And whatever might have been the difficulty of finding *profitable* work, one could scarcely suppose the existence of a parish in which it would not be *possible* to provide some work, were it merely to dig holes and fill them again. But though such was the law, it appears, from the parliamentary returns, that payment for work was the most unusual form in which relief was administered. The poor-rate returns for the year ended the 25th of March 1832 state, that out of L.7,036,968 expended in that year for the relief of the poor, less than L.354,000, or scarcely more than one twentieth part, was paid for work, including work on the roads and in the workhouses. This might easily be accounted for.

In the first place, to afford relief gratuitously proved less troublesome to the parochial authorities than to require work in return for it. Wherever work was to be paid for, there must have been superintendence; but where paupers were the work-people, much more than the average degree of superintendence was necessary. In ordinary cases, all that the superintendent inquired was, whether the workmen had performed an average day's work; and where the work was piece-work, he needed not make even that inquiry. The practice of his trade fixed the market-price of the work, and he paid it without asking whether the workman had been one hour or one day in performing it, or whether it exceeded or fell below his wants. But the superintendent of pauper labourers had to ascertain, not what was an average day's work, or what was the market-price of a given service, but what was a fair day's work for a given individual, his strength and habits considered; at what rate of pay for that work, the number of his family considered, he would be able to earn the sum necessary for his and their subsistence; and, lastly, whether he had in fact performed the amount which, after taking all these elements into calculation, it appeared that he ought to have performed. It will easily be anticipated that this superintendence was very rarely given; and that in far the greater number of instances in which work was professedly required from paupers, in fact no work was done. In the second place, collecting the paupers in gangs for the performance of parish work was found to be more immediately injurious to their conduct than even allowance or relief without requiring any work at all. Whatever might have been the general character of the parish labourers, all the worst of the inhabitants were sure to be amongst the number; and it is well known that the effect of such an association is always to degrade the good, not to elevate the bad. It was amongst these gangs, who had scarcely any other employment or amusement than to collect in groups, and talk over their grievances, that the riots of 1830 appear to have originated. And, thirdly, parish employment did not afford direct profit to any individual. Under the greatest part of the other systems of relief, the immediate employers of labour could throw on the parish a part of the wages of their labourers. They preferred, therefore, those modes of relief which they could turn to their own account, and out of which they could extract profit under the mask of charity.[1]

In some of the agricultural districts, the prevalent mismanagement in this respect had created in the minds of the paupers a notion that it was their right to be exempted from the same degree of labour as independent labourers. But in many places, whilst the labour required by the parish was trifling, the pay equalled or exceeded that of the independent labourer.[2]

The Labour-Rate System.—By an agreement amongst the rate-payers, that each of them should employ and pay out of his own money a certain number of the labourers who had settlements in the parish, in proportion, not to his real demand for labour, but according to his rental or to his contribution to the rates, or to the number of horses that he kept for tillage, or to the number of acres that he occupied, or according to some other scale.

II.—OUT-DOOR RELIEF OF THE IMPOTENT.

The out-door relief to the impotent, using that word as comprehending all except the able-bodied and their families, was subject to less abuse. The great source of poor-law mal-administration was the desire of many of those who regulated the distribution of the parochial funds, to extract from it a profit to themselves. The out-door relief to the able-bodied, and all relief which was administered in the workhouse, afforded ample opportunities for effecting this purpose; but no use could be made of the labour of the aged and sick, and there was little room for jobbing if their pensions were paid in money. Accordingly, it was found that even in places distinguished in general by the most wanton parochial profusion, the allowances to the aged and infirm were moderate.

General Remarks on Out-door Relief.

We have dwelt at some length on out-door relief, because it appears to be the relief which was most extensively given, and because it appears to have contained in itself the elements of an almost indefinite extension; of an extension, in short, which might ultimately have absorbed the whole fund out of which it arose. Amongst the elements of extension were the constantly diminishing reluctance to claim an apparent benefit, the receipt of which imposed no sacrifice, except a sensation of shame, quickly obliterated by habit, even if not prevented by example; the difficulty, often amounting to impossibility, on the part of those who administered and awarded relief, of ascertaining whether any and what necessity for it existed; and the existence in many cases of positive motives on their parts to grant it when unnecessary, or themselves to create the necessity.

From the evidence collected by the Commissioners, it will be seen how zealous must be the agency, and how inperation.

---

[1] "Either the work was completed by two or three o'clock, and the rest of the day spent in idleness, or the men consumed the whole day in the lazy performance of the work of a portion of the day."..."In Pollington, Yorkshire, they send many of them upon the highways, but they only work *four* hours per day. This is because there is not employment sufficient in that way; they sleep more than they work, and if any but the surveyor found them sleeping, they would laugh at them. In Rancliffe they employed a man in the winter of 1830-1831 to look over them; but they threatened *to drown* him, and he was obliged to withdraw."..."In the parish of Mancetter, in the county of Warwick, the overseer stated that young able men received two shillings and sixpence a week, and the magistrates would not allow the parish to employ them more than three days in the week, in order that they might get work for themselves. Upon inquiry, it appeared that their characters soon became so infamous, that no person would employ them, having devoted their spare time to thieving and poaching. In the township of Atherstone, Mr Wellday, a manufacturer, impatient of contributing his property to the encouragement of vice and idleness by paying men without exacting labour, purchased some water-carts himself, for the purpose of giving employment to paupers. The magistrates refused to allow them to be used after twelve o'clock in the day, in order that these men might procure work for themselves. They were also described as becoming the most worthless characters in the town." (Report, p. 37, 38.)

[2] Eastbourne, in Sussex, was a striking example. In that place, in which the average wages earned from individuals by hard work are twelve shillings a week, the parish pays for nominal labour as much as sixteen shillings a week. Two families alone received from it, in the year ended Lady-day 1832, L.92. 4s.; and the wives of the few independent labourers regret that their husbands are not paupers. (Ibid. p. 39.)

tense the vigilance, to prevent fraudulent claims from crowding in under such a system of relief. But it would require still greater vigilance to prevent the *bona fide* claimants from degenerating into impostors; and it was an aphorism amongst the active parish-officers, that "cases which are good to-day are bad to-morrow, unless they are incessantly watched." A person obtained relief upon the ground of sickness; but when he became capable of returning to moderate work, he was tempted, by the enjoyment of subsistence without labour, to conceal his convalescence, and fraudulently extend the period of relief. When it really depended upon the receivers whether the relief should cease with its occasion, it was too much to expect of their virtue that they should, in any considerable number of instances, voluntarily forego the pension.

Another evil connected with out-door relief, and arising from its undefined character, was the natural tendency to award to the deserving more than was necessary, or, where more than necessary relief was afforded to all, to distinguish the deserving by extra allowances. The scale which we have already referred to, promulgated by the magistrates for the town of Cambridge, as well as several others, all directed the parish-officers to reward or encourage the deserving. The whole evidence showed the danger of such an attempt. It appeared that such endeavours to constitute the distributors of relief into a tribunal for the reward of merit, out of the property of others, had not only failed in effecting the benevolent intentions of their promoters, but had become sources of fraud on the part of the distributors, and of discontent and violence on the part of the claimants.

A common consequence was, that to satisfy the clamours of the undeserving, the general scale of relief was raised; but the ultimate result of such a proceeding appears always to have been to augment the distress which it was intended to mitigate, and to render still more fierce the discontent which it was intended to appease. Profuse allowances excited the most extravagant expectations on the part of the claimants, who conceived that an inexhaustible fund was devoted to their use, and that they were wronged to the extent of whatever fell short of their claims. Such relief partook of the nature of indiscriminate alms-giving in its effects, as a bounty on indolence and vice; but the apparently legal sanction to this parochial alms-giving rendered the discontent on denial the most intense. Wherever, indeed, public charities are profusely administered, we hear, from those who are engaged in their administration, complaints of the discontent and disorders introduced.

It appeared from all the Commissioners' returns, that in every district the discontent of the labouring classes was proportioned to the money disbursed in poor-rates or in voluntary charities. The able-bodied unmarried labourers were discontented, from being put to a disadvantage as compared with the married. The paupers were discontented, from their expectations being raised by the ordinary administration of the system, beyond any means of satisfying them.[1]

Those who worked, though receiving good wages, being denominated *poor*, and classed with the really indigent, thought themselves entitled to a share of the "poor funds." Whatever addition was made to allowances under these circumstances excited the expectation of still further allowances, increased the conception of the extent of the right, and insured proportionate disappointment and hatred if that expectation were not satisfied. On the other hand, wherever the objects of expectation had been made definite, where wages, upon the performance of work, had been substituted for eleemosynary aid, and those wages had been allowed to remain matter of contract, employment had again produced content, and kindness became once more a source of gratitude.

Operation.

III.—IN-DOORS RELIEF.

In-doors relief, that which was given within the walls of the poor-house, or, as it was usually, but very seldom properly, denominated, the workhouse, was also subject to great mal-administration. But in by far the greater number of cases it was a large alms-house, in which the young were trained in idleness, and ignorance, and vice; the able-bodied maintained in sluggish and sensual indolence; the aged and more respectable exposed to all the misery incident to dwelling in such a society, without government or classification; and the whole body of inmates subsisting on food far exceeding, both in kind and in amount, not merely the diet of the independent labourer, but that of the majority of the persons who contributed to their support.

Extent of pauperism.

The progress of pauperism, as far as it can be inferred from the progress of expenditure, had been such as is exhibited in the following table; to which the prices of wheat, and the quantities which might have been purchased by the total sums expended, are added, for the purpose of checking, in some measure, the misapprehension which might otherwise arise as to the true value of the sums expended through the fluctuating values of money during the interval to which the table extends.

Years.	Sums expended for Relief of the Poor.	Population o England and Wales.[2]	Average Price of Wheat per Quarter.		Number of Quarters of Wheat for which the money could have been exchanged.
	L.		s.	d.	
1801	4,017,871	8,872,980	115	11	693,234
1803	4,077,891	9,148,314	57	1	1,428,751
1811	6,656,105	10,163,676	92	5	1,440,455
1814	6,294,581	10,755,034	72	1	1,746,474
1815	5,418,846	10,979,437	63	8	1,702,255
1816	5,724,839	11,160,557	76	2	1,503,240
1817	6,910,925	11,349,750	94	0	1,470,409
1818	7,870,801	11,524,389	83	8	1,881,466
1819	7,516,704	11,700,965	72	3	2,080,748
1820	7,330,256	11,893,155	65	10	2,226,913
1821	6,959,249	11,978,875	54	5	2,557,763
1822	6,358,702	12,313,810	43	3	2,940,440
1823	5,772,958	12,508,956	51	9	2,231,094
1824	5,736,898	12,699,098	62	0	1,850,612
1825	5,786,989	12,881,906	66	6	1,740,447
1826	5,928,501	13,056,931	56	11	2,083,221
1827	6,441,088	13,242,019	56	9	2,269,987
1828	6,298,000	13,441,913	60	5	2,084,855
1829	6,332,410	13,620,701	66	3	1,911,671
1830	6,829,042	13,811,467	64	3	2,125,772
1831	6,798,888	13,897,187	66	4	2,049,916
1832	7,036,968	14,105,645	58	8	2,398,966
1833	6,790,799	14,317,229	52	11	2,566,601

[2] The numbers given in this column for the years 1801, 1811, 1821, and 1831, are those ascertained at the enumeration of those years; those stated for the intermediate and for subsequent years are computed from the baptisms and burials, and from the rate of increase, as ascertained at each census.

---

[1] "They, as well as the independent labourers, to whom the term poor is equally applied, are instructed," says Mr Chadwick, "that they have a right to 'a *reasonable* subsistence,' or 'a *fair* subsistence,' or 'an *adequate* subsistence.' When I have asked of the rate-distributors what '*fair*,' or '*reasonable*,' or '*adequate*' meant, I have in every instance been answered differently; some stating they thought it meant such as would give a good allowance of 'meat every day,' which no poor man (meaning a pauper) should be without; although a large proportion of the rate-payers do go without it." It is abundantly shown in the course of this inquiry, that where the terms used by the public authorities are vague, they are always filled up by the desires of the claimants, and the desires always wait on the imagination, which is the worst regulated and the most vivid in the most ignorant of the people. In Newbury and Reading, the money dispensed in poor-rates and charity is as great as could be desired by the warmest advocate either of compulsory or of voluntary relief; and yet, during the agricultural riots, many of the inhabitants in both towns were under strong apprehensions of the rising of the very people amongst whom the poor-rates and charities are so profusely distributed. The violence of most of the mobs seems to have arisen from an idea that all their privations arose from the cupidity or fraud of those intrusted with the management of the fund provided for the poor. (Report, p. 50.)

The following represents the results of the above table at the periods of the decennial census.

Years of the Census.	Cost in Wheat in the proportion of	Cost per head on total Population. s.	d.
1801	7	9	1
1811	14½	13	1
1821	25½	10	7
1831	20	9	9

The foregoing table, however, can by no means be adopted as indicating with any accuracy the real progress of the evil. In the first place, the progress in the amount expended only indicates an increased proportion of pauperism, inasmuch as the increase in the sums expended exceeds the increase in the population. Thus, from the year 1803 to the year 1823, the population increased from nine to twelve millions, whilst the sums expended for relief of the poor increased from four to five and three-fourth millions. This indicates but a small increase in pauperism relatively to the increase of population, and the number of paupers in every hundred persons might have been nearly the same at the two periods compared. We find, however, that the increase in the value of the money expended, as reckoned in the wheat purchaseable by it, was as fourteen to twenty-two, that is, an increase in pauperism which would have exceeded the progress of the population in the proportion of twenty per cent.; and in this period it is to be supposed, either that the numbers of paupers may have increased in the proportion of twenty per cent., or that the effective relief, that is, the quantity of commodities given on the one side and received on the other, had at least increased in the proportion of twenty per cent. But, during all this period, other necessaries and commodities of life had diminished in price in a still greater proportion. Thus it is calculated by Mr Porter,[1] from the extensive data contained in his tables, that the sum of nine shillings and ninepence, the amount of relief per head, in the year 1831, would have purchased as much as seventeen shillings would have bought in 1801.

The sums returned as expended in poor-rates, though, since 1834 and at present, they represent the whole amount of the burthen, did, in fact, up to the year 1834, include but a small part of the whole charge. Of the various modes in which relief was given to the able-bodied labourer, or rather extorted from a portion of the parishioners, two of those above described, viz. relief on the roundsman system, and that on the labour-rate system, were means of casting the burthen of a man's support upon a parishioner, without the levying or expending of any rate. No means exist to enable us to calculate the amount of the burthen thus incurred by the occupiers; and of course the means of calculating the sacrifices of landlords, who made deductions of rate in regard of these charges, are equally wanting. We however find, that amongst the most conspicuous instances in which the rents of a parish had been nearly or entirely absorbed in the relief afforded by these two systems, very small rates had been levied upon the occupiers in money. The Commissioners' evidence, particularly their Appendix (D), is full of instances of this source of indirect and unrecorded loss.[2]

It must also be borne in mind, that in proportion as these modes of relief to the able-bodied were extended, and as the real amount of the burthen was thus concealed, the deterioration of the labourer's habits of industry, involving, not a loss of the particular year, but a permanent destruction of his utility as a labourer, as well as of his prudence and morality, were proceeding in a ratio even more rapid than the progress of these insidious forms of relief.

Objections to amendment,

It might have been hoped, that, under such circumstances, a general feeling would have arisen that these abuses were intolerable, and must be put an end to at any risk or at any sacrifice. But many who acknowledged the evil seemed to expect the cure of an inveterate disease without exposing the patient to any suffering, or even discomfort. They exclaimed against the burthen as intolerable, but objected to any amendment, if it appeared that it must be, or might be, attended with any inconvenience. And amongst all parties, labourers, employers of labourers, and owners of property, many were to be found who thought that they would suffer some immediate injury from any change which should tend to throw the labouring classes on their own resources.

1. On the part of labourers;

The labourer felt that the existing system, though it generally gave him low wages, always gave him easy work. It gave him likewise, strange as it may appear, what he valued more, a sort of independence. He needed not bestir himself to seek work, he needed not study to please his master, he needed not put any restraint upon his temper, he needed not ask relief as a favour. He had all a slave's security for subsistence, without his liability to punishment. As a single man, indeed, his income did not exceed a bare subsistence; but he had only to marry, and it increased. Even then it was unequal to the support of a family, but it rose on the birth of every child. If his family were numerous, the parish became his principal paymaster; for, small as the usual allowance of two shillings a-head might be, yet, when there were more than three children, it generally exceeded the average wages given in a pauperised district. A man with a wife and six children, entitled, according to the scale, to have his wages made up to sixteen shillings a week, in a parish where the usual wages paid by individuals did not exceed ten shillings or twelve shillings, was almost an irresponsible being. All other classes of society were exbjections o Amend-ment.

---

[1] See the Progress of the Nation, by G. R. Porter, Esq. small 8vo, 1836, p. 83.

[2] Mr Cowell's Report contains the examination of a large farmer and proprietor at Great Shelford, who, on 500 acres, situated in that parish, pays ten shillings per acre poor-rate, or L.250 a year. In addition, though he requires for his farm only sixteen regular labourers, he constantly employs twenty or twenty-one. The wages of these supernumerary labourers amount to L.150 a year, and he calculates the value of what they produce at L.50 a year; so that his real contribution to the relief of the poor is not L.250, the sum which would appear in the parliamentary returns, but L.350. In the same Report is to be found a letter from Mr Wedd of Royston, containing the following passages:—

"An occupier of land near this place told me to-day that he pays L.100 for poor-rates, and is compelled to employ fourteen men and six boys, and requires the labour of only ten men and three boys. His extra labour at ten shillings a week, which is the current rate for men, and half as much for boys, is L.130.

"Another occupier stated yesterday that he held 165 acres of land, of which half was pasture. He was compelled to employ twelve men and boys, and his farm required the labour of only five. He is about to give notice that he will quit. Every useless labourer is calculated to add five shillings an acre to the rent of a farm of 100 acres."

It contains also a letter from Mr Nash of Royston, the occupier of a farm in a neighbouring parish, stating that "The overseer, on the plea that he could no longer collect the money for the poor-rates without resorting to coercive measures, and that the unemployed poor must be apportioned amongst the occupiers of land in proportion to their respective quantities, had required him to take two more men. Mr Nash was consequently obliged to displace two excellent labourers, and of the two men sent in their stead one was a married man with a family sickly, and not much inclined to work; the other a single man addicted to drinking."

The subsequent history of these two men appears in Mr Power's Report. One killed a favourite blood mare of Mr Nash's, and the other he was obliged to prosecute for stealing his corn. (Report, p. 55.)

posed to the vicissitudes of hope and fear; he alone had nothing to lose or gain.[1]

It appeared to the pauper, that the government had undertaken to repeal, in his favour, the ordinary laws of nature; to enact that the children should not suffer for the misconduct of their parents, the wife for that of the husband, or the husband for that of the wife; that no one should lose the means of comfortable subsistence, whatever might be his indolence, prodigality, or vice; in short, that the penalty which, after all, must be paid by some one for idleness and improvidence, should fall, not on the guilty person, or on his family, but on the proprietors of the lands and houses encumbered by his settlement. Can we wonder if the uneducated were seduced into approving a system which aimed its allurements at all the weakest parts of our nature, which offered marriage to the young, security to the anxious, ease to the lazy, and impunity to the profligate?

On the art of em-loyers;

The employers of paupers were attached to a system which enabled them to dismiss and resume their labourers according to their daily or even hourly want of them, to reduce wages to the minimum of what would support an unmarried man, and to throw upon others the payment of a part, frequently of the greater part, and sometimes almost the whole, of the wages actually received by their labourers. And even if they paid in rates what they would otherwise pay in wages, they preferred the payment of rates, which occurred at intervals, and the payment of which might from time to time be put off, to the weekly ready-money expenditure of wages. High rates, too, were a ground for demanding an abatement from rent; but high wages were not.[2]

On the rt of pro-ietors.

The owners of rateable property might, at least, have been expected to be favourable to any change which should avert their impending ruin. But of the property liable to poor-rates, there is a portion, and a portion of considerable importance, less from its value, than from the number of rate-payers amongst whom it is divided, and their influence in vestries, which not only is, in practice, exempted from contributing to the parochial fund, but derives its principal value from the mal-administration of that fund. This property consists of cottages or apartments inhabited by the poor. In almost all places the dwellings of the poor, or at least of the settled poor, were exempted from rates, and, besides, the rent was, in a very large proportion, paid by the parish. The former practice enabled the proprietor often to increase the rent by the amount of rate remitted, and always to be an owner of real property, and yet escape the principal burdens to which such property was subjected. The latter practice gave him a solvent tenant, and, if he had influence with the vestry or with the overseer, a liberal one.

Objections to Amendment.

Of the higher classes of landlords, those who reside in towns seldom took much part in parochial government, or had any distinct ideas as to the extent or the effects of its mismanagement; and the majority of those who had become familiarized with the abuses of the villages seem to have acquired habits of thinking and feeling and acting which unfitted them to originate any real and extensive amendment, or even to understand the principles upon which it ought to be based. To suppose that the poor are the proper managers of their own concerns; that a man's wages ought to depend on his services, not on his wants; that the earnings of an ordinary labourer are naturally equal to the support of an ordinary family; that the welfare of that family naturally depends on his conduct; that he is bound to exercise any sort of prudence or economy; that anything is to be hoped from voluntary charity; are views which many of those who have long resided in pauperised rural districts seem to have rejected as too absurd for formal refutation.

---

[1] Even in Barnard Castle, in Durham, Mr Wilson states, that if any remonstrance is made on account of the applicant's bad character, the reply of the magistrate commonly is, "the children must not suffer for it."

The following answers are specimens of the feeling and conduct in the southern districts:—"The answer given by the magistrates, when a man's bad conduct is urged by the overseer against his relief, is, 'We cannot help that; his wife and family are not to suffer because the man has done wrong.'"

"Too frequently petty thieving, drunkenness, or impertinence to a master, throw able-bodied labourers, perhaps with large families, on the parish funds, when relief is demanded as a right, and, if refused, enforced by a magistrate's order, without reference to the cause which has produced his distress, viz. his own misconduct, which remains as a barrier to his obtaining any fresh situation, and leaves him a dead weight upon the honesty and industry of his parish."

Mr Stuart states, that in Suffolk, children deserted by their parents are in general well taken care of, and that the crime of deserting them is largely encouraged by the certainty that the parish must support the family. Even the inconvenience which might fall on the husband by the punishment of his wife for theft, is made the subject of pecuniary compensation at the expense of the injured parish. Under what other system could there be a judicial instrument concluding thus:—

"And whereas it appears to us that the wife of the said Robert Reed is now confined in the house of correction at Cambridge, and that he is put to considerable expense in providing a person to look after his said five children, we do therefore *order* the churchwardens and overseers of the poor of the said parish, or such of them to whom these presents shall come, to pay unto the said Robert Reed the sum of eleven shillings weekly and every week, for and towards the support and maintenance of himself and family, for one month from the day of the date hereof. Given under our hands and seals this twentieth day of February, in the year of our Lord one thousand eight hundred aud thirty-three." (Report, p. 59.)

[2] In Mr Richardson's instructive statement of the reforms effected by Mr Litchfield, in Farthingoe, Northamptonshire, we find that Mr Litchfield has been opposed, not only by the labourers, but by the farmers; first, because they grudged giving the labourer with no children eight shillings a week; secondly, because they were afraid to displease the labourer who had two children, and preferred head-money; and, thirdly, because they were fearful lest, if the rates were lowered, their rents would be raised; and that they encouraged the labourers, at first openly, and afterwards covertly, in their attempts to deter Mr Litchfield by menaces and insult.

"When a valuer," says Mr Cowell, "values a farm to an in-coming tenant, or fixes the rent from time to time (in these parts they have no leases), he says, 'What are your poor-rates?' If the tenant answer, 'Rates are low, but wages are high,' the valuer says, 'I have nothing to do with *wages*, that is your affair; but *rates* are a *positive thing*, and I allow for *them*.' This Mr Ellman considers as a bad custom, as it holds out an inducement to the farmer to prefer low wages and high rates. Tenants at will, says Mr Cogshill, too often think, the more poor-rates the less rent. Confidence between landlord and tenant seems quite lost. I have witnessed a good deal of this."

The following replies to question 36 of the Commissioners' Rural Queries are further testimonies to the same effect.

"I think the poor-laws have not diminished the capital, but rather the rent of the landlord, as the tenant considers rents and rates as payment for the farm, and one can only be increased at the expense of the other."

"The farmers are aware that, excepting in cases of long tenures and very sudden augmentation of rates, the burden does not at all affect them. It is a rent paid to the parish instead of the landowner."

"It should be understood that poor-rates are deducted in all calculations for rent; and that landlords pay them, and not the farmers."

"Capital is decreasing, from the loose manner in which the laws are administered, and the tenants feeling that they do not in effect pay the rates, but the landlord. I cannot otherwise account for the apathy with which they view, and the tenacity with which, in many instances, they defend abuses." (Report, pp. 60, 61, 62.)

Effects of system on proprietors,

Yet were the effects of the system such, that it might reasonably have been expected that any plan affording a reasonable prospect of a remedy would have been welcomed by all classes. The proprietors, who had been mulcted every year of a larger and larger portion of their income, were not only deprived of the benefits to their property naturally dependent on a constant increase of the population and in the consumption of produce, each such increase bringing with it an accumulating charge of pauperism. Instances of the total abandonment of the land had not yet become numerous, but the approach towards it was in many cases imminent, and in all certain and rapid;[1] whilst every diminution of cultivation was seen to have a double effect in increasing the rate on the remaining cultivation, the number of unemployed labourers being increased at the same instant as the fund for payment of rates was diminished; and the abandonment of property once begun, gave induced cause to proceed at an accelerated ratio.

on employers,

The employers found the services of their labourers deteriorated both by the loss of industry, skill, and intelligence, which can only be secured by a recognition, on the part of the labourer, of the value to himself of such qualities; and they had to contend with many other habits of insolence and insubordination, the natural results of the labourer's ceasing to depend upon his good character.

on the labourers.

But by far the severest sufferers were those for whose benefit the system was supposed to have been introduced and perpetuated; we mean the labourers and their families. Amongst these, the effects were not confined to those actually relieved. Instances were everywhere found in which the prudence and forethought of a labourer became his punishment instead of a reward. So onerous was the entire support of a man with a large family, and entirely destitute, that the rate-payers in agricultural parishes were generally agreed in employing such a one, so as to keep his family off the rates, in preference to another who had not married, or who had no family, or who had the means, by greater prudence or by any good fortune, for a while to support himself.[2] The system, in short, was this.

Piece-work was refused to the single man, or to the married man, if he had any property, because they could exist upon day-wages; it was refused to the active and intelligent labourer, because he could earn too much. The enterprising man, who had fled from the tyranny and pauperism of his parish to some place where there was a demand and a reward for his services, was driven from a situation which suited him, and an employer to whom he was attached, by a labour-rate or some other device against non-parishioners, and forced back to his settlement to receive as alms a portion only of what he was obtaining by his own exertions. He was driven from a place where he was earning, as a free labourer, twelve or fourteen shillings a week, and was offered road-work as a pauper, at sixpence a day, or perhaps to be put up by the parish authorities to auction, and sold to the farmer who would take him at the lowest allowance.

Can we wonder, then, if the labourer abandoned virtues of which this was the reward; if he gave up the economy in return for which he had been proscribed, the diligence for which he had been condemned to involuntary idleness, and the prudence, if it can be called such, which diminished his means just as much as it diminished his wants? Can we wonder if, smarting under these oppressions, he considered the law, and all who administered the law, as his enemies, the fair objects of his fraud or his violence? Can we wonder if, to increase his income, and to revenge himself on the parish, he married, and thus helped to increase that local excess of population which was gradually eating away the fund out of which he and all the other labourers of the parish were to be maintained?

But though the injustice perpetrated upon the man who struggled, as far as he could struggle, against the oppression of the system, who refused, as far as he could refuse, to be its accomplice, was at first sight the most revolting, the severest sufferers were those that had become callous to their own degradation, who valued parish support as their privilege, and demanded it as their right, and complained only that it was limited in amount, or that some sort of labour or confinement was exacted in return. No man's principles can be corrupted without injury to society in general; but the person most injured is the person whose principles have been corrupted. The constant war which the pauper had to wage with all who employed or paid him, was destructive of his honesty and his temper; as his subsistence did not depend on his exertions, he lost all that sweetens labour, its association with reward, and got through his work, such as it was, with the reluctance of a slave. His pay, earned by importunity or fraud, or even violence, was not husbanded with the carefulness which would be given to the results of industry, but wasted in the intemperance to which his ample leisure invited him. The ground upon which relief was ordered to the idle and dissolute was, that the wife and children must not suffer for the vices of the head of the family; but as that relief was almost always

---

[1] See the Commissioners' Report, page 65, where instances like the following are given from all parts of the country. The present is taken from Leicestershire, a county not within the range of the extreme operation of pauperism. "Mr Pilkington's description of several places in Leicestershire is equally alarming. In Hinckley he found the poor-rate exceeding one pound an acre, and rapidly increasing, and a general opinion that the day is not distant when rent must cease altogether. On visiting Wigston Magna, in November 1832, he was informed that the value of property had fallen one half since 1820, and was not saleable even at that reduction. It does not appear, indeed, that it ought to have sold for more than two or three years' purchase, the net rental not amounting to L.4000 a year, and the poor-rate expenditure growing at the rate of L.1000 increase in a single year. And on his return to that neighbourhood, three months afterwards, the statement made to him was, that property in land was gone; that even the rates could not be collected without regular summons and judicial sales; and that the present system must insure, and very shortly, the total ruin of every individual of any property in the parish. We cannot wonder, after this, at the statement of an eminent solicitor at Loughborough, that it is now scarcely possible to effect a sale of property in that neighbourhood at any price."

The following answers, taken from a multitude of others of a similar nature, contained in Appendix (B), are to the same effect:—

"Annual value of the real property, as assessed April 1815, L.3390; annual value of the real property, as assessed November 1829, L.1959. 5s. It has undoubtedly fallen in value since the last valuation, *i. e.* in the last two years; and the population has been more than trebled in thirty years—1801, 306; 1811, 707; 1821, 897; 1831, 938; and that in spite of an emigration of considerable amount, at the parish expense, in 1829. The eighteen-penny children will eat up this parish in ten years more, unless some relief be afforded us." (Report, pp. 65, 66.)

[2] See striking evidences of these influences in the Report, page 78. "Will it be believed that such is not merely the cruelty, but the folly, of the rate-payers in many places, that they prohibit this conduct (the anxiety of an independent labourer to make provisions for his family by his own exertions)—that they conspire to deny the man who, in defiance of the examples of all around him, has dared to save, and attempts to keep his savings, the permission to work for his bread? Such a statement appears so monstrous, that we will substantiate it by some extracts from our evidence."

Sir Harry Verney, in a communication which will be found in Appendix (C), says, "In the hundred of Buckingham, in which I act as a magistrate, many instances occur where labourers are unable to obtain employment, because they have property of their own. For instance, in the parish of Steeple Claydon, John Lines, formerly a soldier, a very good workman, is refused employment because he receives a pension. The farmers say that they cannot afford to employ those for whom they are not bound by law to provide."

Effects of System.

given into the hands of the vicious husband or parent, this excuse was obviously absurd. It appears from the evidence that the great supporters of the beer-shops were the paupers.

The worst of results, however, are still to be mentioned. In all ranks of society, the great sources of happiness and virtue were the domestic affections, and this was particularly the case amongst those who had so few resources as the labouring classes. Now pauperism seems to have become an engine for the purpose of disconnecting each member of a family from all the others, and of reducing all to the state of domesticated animals, fed, lodged, and provided for by the parish, without mutual dependence or mutual interest.[1]

CHAPTER IV.

REMEDIAL MEASURES PROPOSED AND ADOPTED.

Remedial Measures.

It has been a frequent subject of public remark, that the remedial measures proposed by the Commissioners of Inquiry were the result of a process more deliberately and completely inductive than was to be found in any other instance of English, or indeed of any legislation. It is impossible to give any impression of the extent and value of the evidence upon which their conclusions were supported, otherwise than by a repetition of nearly the whole of the Report in which their remedial measures were detailed. This is impossible in the space allotted to this article; but to those interested, not only in the present question, but in acquainting themselves with a most masterly example of legislative investigation, no greater service can be done than to refer them to the document itself, which has been characterized by one of the most eminent, candid, and experienced of our statesmen, as one of the ablest state-papers he ever read.

The following description will exhibit a mere summary of the remedies proposed and adopted, with little more than hints of the reasonings upon which they were founded.

The Commissioners by no means adopted the opinion that a poor-law could, in a community like ours, be dispensed with. They found that the most pressing of the evils of the poor-laws were those connected with the relief of the able-bodied, and to these they suggested their first remedies. They assumed as their principle of administration, that the public is warranted in imposing such conditions on the individual relieved, as are conducive to the comfort either of the individual himself, or of the country at large at whose expense he is relieved.

rinciple of lminister- 'g relief.

They proposed, then, as the first and most essential of all conditions of relief, that the situation of the pauper, upon the whole, should not be made really or apparently so eligible as the situation of the independent labourer of the lowest class. It was shown throughout the evidence, that as the condition of the pauper class was elevated, the condition of the independent class was depressed, their industry impaired, their employment rendered unsteady, and its remuneration diminished. Such persons, therefore, were under the strongest inducements to quit the *less eligible class of labourers*, and enter the *more eligible class of paupers*. The Commissioners maintained that the converse would be, and was found to be, the effect of placing the pauper class in its proper position below the condition of the independent labourer. They found, on a large examination of the cases of strict administration of relief on the principle of letting the labourer find in the parish the hardest taskmaster and the worst paymaster he can have, that the parish had always become his last, and not his first, resource; and they found largely exemplified those specific results which invariably ensue from such an administration.

Effects of this.

The first and immediate effect, was the conversion of the able-bodied paupers into independent labourers. The second result, indeed a corollary of the first, was the reduction of the parochial expenditure, constituting an increase of the fund for the employment of independent labourers. The third effect, closely connected with and following the absorption of able-bodied paupers, and their conversion into independent labourers, was the rise in wages. The fourth class of the observed specific effects was the diminution, not only of pauper-marriages, but of those imprudent marriages contracted with the knowledge and confidence that the worst result to be apprehended was an eventual dependence upon the poor-rate. The fifth and last specific effect dwelt upon by the Commissioners, and illustrated by their evidence, was the diminution of crime, and the contentment of the labourers increasing with their industry.

The Commissioners, in endeavouring to obtain the general adoption of this principle, cautiously avoided the recommendation of speculative remedies; they dwelt anxiously and emphatically upon the necessity and the safety of adopting a course of legislation which may be considered as wholly experimental. They propose, therefore, no changes in the principle of the law, but confine their recommendations to this, that the means which have been found the most effective in practice, should be applied wherever it was found applicable with the prospect of a beneficial result.

To secure this operation, they recommend the adoption of a new and more responsible agency to co-operate with and control that which had been found for the most part inefficient, or greatly efficient for mischief. Some excrescences in the law they propose to lop off, but no additions beyond the improvement of the agency were proposed to be introduced in the principle of the statute of Elizabeth, and the succeeding legislation. They recommend, therefore, "that those modes of administering relief which have been

---

"The effect of allowance," says Mr Stuart, "is to weaken, if not to destroy, all the ties of affection between parent and child. Whenever a lad comes to earn wages, or to receive parish relief on his own account" (and this we must recollect is at the age of fourteen), "although he may continue to lodge with his parents, he does not throw his money into a common purse, and board with them, but buys his own loaf and piece of bacon, which he devours alone. The most disgraceful quarrels arise from mutual accusations of theft; and as the child knows that he has been nurtured at the expense of the parish, he has no filial attachment to his parents. The circumstances of the pauper stand in an inverted relation to those of every other rank in society. Instead of a family being a source of care, anxiety, and expense, for which he hopes to be rewarded by the filial return of assistance and support when they grow up, there is no period in his life in which he tastes less of solicitude, or in which he has the means of obtaining all the necessaries of life in greater abundance; but as he is always sure of maintenance, it is in general the practice to enjoy life when he can, and no thought is taken for the morrow. Those parents who are thoroughly degraded and demoralized by the effects of 'allowance,' not only take no means to train up their children to habits of industry, but do their utmost to prevent their obtaining employment, lest it should come to the knowledge of the parish-officers, and be laid hold of for the purpose of taking away the allowance."

"At Princes Risborough, we turned over the minute-book of the Select Vestry, and found the following entries:

"'Samuel Simmons's wife applied to be allowed something for looking after her mother, who is confined to her bed; the mother now receives 3s. 6d. weekly. To be allowed an additional 6d. for a few weeks.'

"'David Walker's wife applied to be allowed something for looking after her father and mother (old Stevens and his wife), now ill, who receive 6s. weekly. To be allowed 1s. weekly.'

"'Mary Lacy applies for something for waiting on her mother, now ill. Left to the governor.'

"'Elizabeth Prime applies to have something allowed for her sister looking after her father, now ill. Left to the governor.'" (Report, pp. 96, 97.)

Remedial Measures.

tried and found beneficial, be generally enforced" (Report, p. 261); and "that the practice of giving relief in well-regulated workhouses, and the abolition of partial relief to the able-bodied, having been tried and found beneficial, be extended to all places." (*Ibid.* p. 262.)

Workhouse recommendations.

The first and chief specific measure recommended by them was thus described:—" *First*, That, except as to medical attendance, and subject to the exception respecting apprenticeship hereinafter stated, all relief whatever to able-bodied persons, or to their families, otherwise than in well-regulated workhouses (*i. e.* places where they may be set to work according to the spirit and intention of the 43d of Elizabeth), shall be declared unlawful, and shall cease, in manner and at periods hereafter specified; and that all relief afforded in respect of children under the age of sixteen shall be considered as afforded to their parents." (*Ibid.* p. 262.)

This adoption of the workhouse and its restrictions as the condition upon which relief was to be administered, was advised, because it would operate, in the first place, as a self-acting test of the claim of the applicant, it being urged " That it is demoralizing and ruinous to offer to the able-bodied of the best characters more than a simple subsistence. The person of bad character, if he be allowed anything, could not be allowed less. By the means which we propose, the line between those who do, and those who do not, need relief, is drawn, and drawn perfectly. If the claimant does not comply with the terms on which relief is given to the destitute, he gets nothing; and if he does comply, the compliance proves the truth of the claim, namely, his destitution. If, then, regulations were established and enforced with the degree of strictness that has been attained in the dispauperised parishes, the workhouse doors might be thrown open to all who would enter them, and conform to the regulations. Not only would no agency for contending against fraudulent rapacity and perjury, no stages of appeals (vexatious to the appellants and painful to the magistrates), be requisite to keep the able-bodied from the parish; but the intentions of the statute of Elizabeth, in setting the idle to work, might be accomplished, and vagrants and mendicants actually forced on the parish, that is, forced into a condition of salutary restriction and labour. It would be found that they might be supported much cheaper under proper regulations than when living at large by mendicity or depredation." (*Ibid.* p. 264.)

In the *second* place, it was observed by the Commissioners, that " Little need be said on the next effect of the abolition of partial relief (even independently of workhouse regulations), in drawing a broad line of distinction between the paupers and the independent labourers. Experience has shown, that it will induce many of those whose wants arise from their idleness, to earn the means of subsistence; repress the fraudulent claims of those who have now adequate means of independent support; and obtain for others assistance from their friends, who are willing to see their relations pensioners, but would exert themselves to prevent their being inmates of a workhouse." (*Ibid.* p. 276.)

In the *third* place, it was relied on to remove much of the evil arising from the situation of the distributors of relief, who, having many modes of relief at their disposal, were rendered liable to odium and revenge when they chose a more strict mode of administration, and were liable to be seduced by all the motives which the love of popularity, fear, or the cajolery, importunity, or menaces of the applicant presented, to adopt a lax administration.

How far adopted.

These reasons appear to have entirely prevailed with the legislature, who accordingly adopted them in principle, only modifying them thus far in their form. Combining the effect of this recommendation with the one subsequently to be described, the institution of a central board, the legislature—not fixing any determinate period, but bearing in mind the magnitude of the amount of the existing out-door relief to able-bodied men and their families, with the possibility that the means might not suffice at the periods to be specified, for affording all the workhouse relief that might be required upon a sudden cessation of all other relief—adopted the plan of leaving the determination of the period at which out-door relief should cease, and relief in the workhouse become the invariable rule, to the judgment of the central board; that board having power to adopt a different course in different districts, to adopt the workhouse relief entirely and at once where the means existed, and in others to prepare the way by procuring workhouses, and the gradual substitution of relief in kind for relief in money, and by other intermediate and preparatory operations. (See the Act, sect. 52.) As a consequence of adopting this course, all restrictions imposed by previous acts upon officers, with a view of preventing them from applying the workhouse to able-bodied men, are repealed (sect. 53); and authority to direct the purchase, the furnishing, and the management of workhouses is given to the central board.

Parents' liability.

The legislature adopted, without change, except by way of addition, so much of this recommendation as has the effect of identifying the relief to an unemancipated child with the relief to the parent; the intended effect being to render the parent as responsible for providing for his children as for himself, and subject to the same consequences of neglect in either case, so that he cannot seek relief for his child, without submitting to the condition upon which alone he could obtain it for himself, or otherwise. The legislature adopted with this recommendation these expansions and additions: Relief of the wife is made relief to the husband; of the child, to the parent, to the father if living, or otherwise to the widow (sect. 56); and of the bastard child, to the mother (sect. 71). Moreover, a man marrying since the act, is made liable to maintain the children which his wife has at the time of her marriage, until they attain the age of sixteen, or until her death (sect. 57); this last provision being made with the view that the man is liable to all the civil obligations of his wife existing at the time of her marriage, excepting this obligation, which must commonly have been of all her obligations the most notorious. As the law stood, a woman's family, legitimate or illegitimate, was, by her marriage, cast on the parish for support, and the allowances made to them constituted an annuity to the married couple, forming an inducement of extraordinary frequency to marriages in all other respects the most improvident.

Central control.

The Commissioners' second specific measure was thus proposed:—" We recommend, therefore, the appointment of a central board to control the administration of the poor-laws, with such assistant commissioners as may be found requisite; and that the commissioners be empowered and directed to frame and enforce regulations for the government of workhouses, and as to the nature and amount of the relief to be given and the labour to be exacted in them; and that such regulations shall, as far as may be practicable, be uniform throughout the country." (Report, p. 296.)

The reasons for the establishment of this agency are eloquently and most instructively stated in the Report; especially the reasons for relying rather upon a constantly acting agency, with the means of judging at every moment of the extent to which its measures would then apply, in preference to relying upon a mere legislative enactment, however valuable the principle involved, or stringent its provisions might be. Instances of the most striking kind are given, not only of the failure of such enactments, but of their conversion to purposes directly contrary to their object, where no authority was erected responsible for conducting their operations. The other grounds for this recommendation were chiefly the impossibility of choosing a succession of overseers or other annual officers with ap-

Remedial Measures.

propriate knowledge, still less with the enlarged experience of the means to be used, or an enlightened appreciation of the objects to be attained; next, the short duration of the office, which, even where able officers are occasionally found, prevents the continued application of their experience, precisely at the time when their efficiency has become the greatest; next, the division of the districts for which they served, preventing co-operation or the dispersion of the knowledge obtained on one spot over the others to which it might be applicable. Scarcely an instance was found of a parish being dispauperised, the example of which was followed even by a single adjoining parish. Reference was also made to the inadequacy of the motives of any officer to support a sound administration: his responsibility little or none,—his gain no more than that of every other rate-payer occupying as largely as himself,—the loss of time and of energy,—the danger of misapprehension by those he sought to serve, and of failure in the whole object, great,—the certainty of odium from the pauper and from the prejudiced amongst his fellow-parishioners, and of jealousy from rival officers, being inevitable,—whilst, on the other hand, the strength of the interests in abusive administration, by which one man may make to himself a gain of the losses of many, whilst by the best administration he can only save himself from the loss falling to the share of one,—the confederacy of those who recognise their interest in such corrupt gain,—the popularity to be acquired by liberality in the disposal of funds contributed by others,—form some few of the motives to uphold the prevailing abusive administration. In these views the Commissioners adopted the conclusion, that whatever might be the intentions of the legislature, they would be best carried out by a permanent authority, accumulating experience in itself, independent of local control, uninterested in favour of local abuse, but responsible for carrying into effect the law which it was appointed to execute. This recommendation was adopted by the legislature, according to the spirit in which it was made. A board of three commissioners was to be appointed by the king (sects. 1 to 11), themselves appointing assistant commissioners, capable of receiving the powers of the commission by delegation (sects. 8 to 13); the commission having power to direct and control the whole administration of relief throughout England and Wales, and especially the government of workhouses, and it being left to them to determine the extent to which the measures to be carried out should be rendered uniform.

nion of ishes.

But the districts for the administration of relief, that is, parishes by the statute of Elizabeth, and town-lands by the 13th and 14th Charles II., had been fortuitously created, sometimes containing but one householder, sometimes containing a population exceeding 100,000. There were in 1831, in England and Wales, fifty-six parishes containing less than ten persons, and which may be therefore calculated, one with the other, to contain but two adult males; a hundred and forty-eight parishes containing but from ten to twenty persons, the largest of these on the average containing five adult males; and five hundred and thirty-three parishes containing from twenty to fifty persons, the largest of which would give less than twelve adult males per parish. Taking into consideration the small number of our adult male population who can read and write, a conception may be formed of the absurdity of the expectation, that every parish can adequately supply a constant succession of annual officers competent to perform the very complicate and difficult duties of the levier and collector of rates, and distributor of relief.

Remedial Measures.

The evidence shows a large proportion of the overseers exercising these functions, though unable otherwise to sign their accounts than by their mark, attested by the justice's clerk. But if it was difficult to find a supply of officers for these districts, it would have been preposterous to expect that each district should supply itself with an efficient workhouse, however indispensable that should be as a means of protection to its population. It was found, on an examination of the largest, of the smallest, and of the intermediate parishes, in the seven first counties in England, taken in alphabetical order, that the largest districts gave the lowest cost per head, the smallest gave the greatest cost per head, and those of intermediate size an intermediate cost. The results are thus stated in the Report: The sixty-seven largest parishes gave 9s. 0¾d. per head in population; the sixty-six intermediate gave 14s. 4d. per head in population; the sixty-seven least gave 14s. 11¾d. per head in population; whilst, if we take all England, there are the still more striking results, viz. the hundred absolutely largest parishes, containing a population of 3,196,064, gave 6s. 7d. per head; the hundred intermediate parishes, containing a population of 19,841, gave 15s. per head; the hundred least parishes from which poor-rate returns are made, with a population of 1708, gave L.1. 11s. 11½d. per head.

Such are the results as tested by the cost of administration in the larger and in the smaller districts; but the moral effects in producing pauperism were as disastrous in the smaller districts. The Commissioners observe, that they "have no recent returns of proportions of paupers in the parishes referred to in the preceding statement; but on referring to the parliamentary returns of the number of paupers in each parish in the years 1803 and 1813, it appears that the number of persons relieved in the large and small parishes bore some proportion to their relative amount of rates. In the three hundred parishes of which the comparative amount of the poor's rates on the population has been stated, the average number of persons relieved was, in the hundred largest parishes, in 1803, 1 in 16, or 6¼ per cent.; in 1813, 1 in 13, or 7¾ per cent.: in the hundred intermediate ditto, in 1803, 1 in 10, or 10 per cent.; in 1813, 1 in 8, or 12½ per cent.; and in the hundred smallest ditto, in 1803, 1 in 6, or 16⅔ per cent.; in 1813, 1 in 4, or 25 per cent." And the progress of the disaster was shown to be most rapid in the smallest districts: thus, "the increase of pauperism on population, from 1803 to 1813, was, in the hundred largest parishes, 1½ per cent.; in the hundred intermediate ditto, 2½ per cent.; and in the hundred smallest ditto, 8⅓ per cent." The economy of extended management was thus experimentally proved in every possible direction, and the moral interests were shown to be the same with the pecuniary.

The Commissioners entered largely into the examination of this subject in all its bearings, and ended by recommending "that the central board be empowered to cause any number of parishes which they may think convenient, to be incorporated for the purpose of workhouse management, and for providing new workhouses where necessary; to declare their workhouses to be the common workhouses of the incorporated district, and to assign to those workhouses separate classes of poor, though composed of the poor of distinct parishes, each distinct parish paying to the support of the permanent workhouse establishment, in proportion to the average amount of the expense incurred for the relief of its poor for the three previous years, and paying separately for the food and clothing of its own paupers." This recommendation was adopted by the legislature in all points. The common workhouses are provided for by sections 23, 24, 26; the maintenance of the workhouse and establishment charges is fixed in the proportion of the average expenditure of the three previous years by section 28, with the power of taking future averages; the cost of the maintenance of its individual paupers being borne by each parish, under section 26.

Accounts.

The necessity of providing for a clear and uniform system of accounts was shown in an extraordinary manner in the inquiries of the Commission; but it is too obvious to re-

Remedial Measures.

quire further remark, and the previous observations show in some measure the difficulty of obtaining efficient parochial officers, and the necessity of resorting to further means to attain the object.

The Commissioners recommended "that the central board be empowered and required to take measures for the general adoption of a complete, clear, and, as far as may be practicable, uniform system of accounts." This recommendation was also adopted in full by the legislature, the Commissioners' powers being given by section 15, the audit being provided for by sections 46 and 89.

Paid and permanent officers.

Upon the subject of officers, the Commissioners recommend, "that the central board be empowered to incorporate, for the purpose of appointing and paying permanent officers, and for the execution of works of public labour;" and "that the central board be directed to state the general qualifications which shall be necessary to candidates for paid offices connected with the relief of the poor, to recommend to parishes and incorporations proper persons to act as paid officers, and to remove any paid officers whom they shall think unfit for their situations."

This also is adopted in the 46th section of the act, except that the Commissioners have no power to recommend the persons to act as paid officers, but have ample powers to determine, by regulation, the qualification and removal of all paid officers. The chief remaining recommendation affecting the general administration of the law by the Commissioners was, "that the board be required to submit a report annually to one of your majesty's principal secretaries of state, containing, 1. an account of their proceedings; 2. any further amendments which they may think it advisable to suggest; 3. the evidence on which the suggestions are founded; 4. bills carrying those amendments, if any, into effect, which bills the board shall be empowered to prepare with professional assistance."

This is also adopted, as far as the annual report is concerned, without, however, any definition in the act of the subjects upon which the Commissioners are to report, that being left to their discretion and to the condition of affairs to determine, section 5; they are to make a current record of their proceedings, section 4; and they are bound to give any information respecting their proceedings which the secretary of state may at any time call for, section 6.

Remedia Measure

Settleme law.

The remaining recommendations of the Commissioners relate chiefly to the law of settlement and that of bastardy. These subjects were more important when all who could gain a settlement might claim the benefit of that settlement, without any check. The improved administration, especially the inducements which now act as restraints upon the applications for relief, have diminished the motives to the voluntary pauper to fix his settlement in a good parish, and have proportionally diminished the danger to parishes, both from the attempts of the pauper, and from the exertions of the officers of other parishes to shift their burthens, by giving to their own poor the means to acquire a new settlement elsewhere. The most important change in the settlement law recommended and adopted, was that which repealed the settlement by hiring and service; a settlement which impeded the free circulation, the effects of which in restraining labourers to their parishes, and creating a reliance on their parishes, was shown to constitute the great plague-spot of the poor-law system as it then existed.[1] This law of settlement was repealed by the 64th and 65th sections, as were the settlement by occupation of a tenement without payment of poor-rates by the 66th, and that by apprenticeship to the sea-service by the 67th; and improvements in the whole law of removal, by which great wrong had been mutually done by parishes one to the other, were introduced by the 79th and following sections.

Bastardy law.

The bastardy law, which had made it a more prudent speculation for a woman to have a family of bastard children than to have an equal number of legitimate children, by enabling her to cast off the burthen of the children, which the widow could not do, and thus to enforce from the parish, and through the parish from whomsoever she charged as the father, such a contribution as would induce her to keep them. This law, also, by subjecting the person charged as the father, and who could not give security to pay, to imprisonment, was a means of terror by which a woman was often enabled to compel a marriage; a means to which recourse was had to an extent almost incredible.[2]

These demoralizing influences the legislature, by the re-

---

[1] "The Reverend R. R. Bailey, chaplain to the Tower, who has had extensive opportunities of observing the operation of the poor-laws in the rural districts, was asked,—'Can you give any instances within your own knowledge, of the operation of the existing law of settlement? I was requested by Colonel Bogson, Kesgrove House, to furnish him with a farming bailiff. I found a man in all respects qualified for his situation; he was working at nine shillings a week in the parish where I lived. The man was not encumbered by a family, and he thankfully accepted my offer; the situation was, in point of emolument, and comfort, and station, a considerable advance; his advantages would have been doubled. In about a week he altered his mind, and declined the situation, in consequence, as I understood, of his fearing to remove from what was considered a good parish to a bad one, the parish to which it was proposed to remove him being connected with a hundred house, in which there is more strict management. I was requested by a poor man, whom I respected, to find a situation for his son in London. The son was a strong young man, working at that time at about eight shillings a week. I eventually succeeded in getting him a good situation of one guinea per week in London, where his labour would have been much less than it was in the country; but when the period arrived at which he was expected in London, he was not forthcoming. It appeared he had altered his mind, and determined not to take the place; as I understood, his reason for refusing to accept it arose from a reluctance to endanger his settlement in his parish. Such are the instances which are continually presented to my observation with respect to the operation of the present system of settlement.'

"Among our present modes of conferring a settlement," says Mr Russell, in the replies to which we have already adverted, "that by hiring and service is incomparably the most pernicious; it tells the poor man that he shall encounter a prohibitory duty in every market in which he attempts to dispose of the only commodity he must live by selling; it shuts the door against the most respectable and advantageous employment in which a servant can engage; by abridging the term, it impairs the strength of the connection between him and his master; and it not only drives the servant from his place, but often betrays him, during the interval between his being discharged from one house and hired at another, into bad company, dissipation, and vice. (Report, p. 155–6.)

[2] The following is an instance of the testimony as to the operation of the act, given in a letter from the overseer of Llanasa, in the county of Flint, in answer to an inquiry from the board, "Why the bastards in the parish are so few now? I can only observe, that, in the first place, we never force the putative father to marry the mother; and we compel the mother, as well as the father, to pay her quota towards the maintenance of the child. This was our simple mode of treating the business. One thing I must observe, and it tells well for the new poor-law act, that in our parish we have from fifteen to twenty weddings in the year, and it seldom happened that at the ceremony the bride did not think it decent and requisite (I am now speaking of the lower order of persons) to conceal her shape under a cloak. But in the eighteen marriages which we have had since last August, all the ladies, except one, retained their virgin shape, and appeared without the mantle." (First Annual Report, pp. 57, 58.)

"An unmarried girl, upon leaving the workhouse after her fourth confinement, said to the master, 'Well, if I have the good luck to have another child, I shall draw a good sum from the parish; and, with what I can earn myself, shall be better off than any married woman in the parish;' and the master added, that she had met with the good luck she hoped for, as she told him, a short time before I was at Holbeach, that she was five months gone with child. I asked him what she had for each child? He answered, two

Remedial Measures.

commendation of the Commissioners, deprived of further effect, *first*, by rendering the mother of a bastard liable for its maintenance, in the like manner as a widow for the maintenance of her legitimate children, section 71; *secondly*, by rendering it unlawful to pay to her any sums which the putative father might be compelled to contribute for the reimbursement of the parish; and, *thirdly*, by rendering it necessary that evidence additional to that of the mother should be required to corroborate her charge against the person accused of being the father.

Such, in the main, were the recommendations of the Commissioners, the views with which they were urged, and those with which they were adopted by the legislature. Other provisions were also adopted, necessary, indeed, to give effect to these more important purposes, but not of sufficient importance, or sufficiently characteristic of any great principle, to require remark here.

CHAPTER V.

EFFECTS OF THE AMENDED SYSTEM.

It has been seen that one of the duties with which the Commissioners were charged was that of reporting annually to the secretary of state. The Commissioners having superintended the administration for four years from August 1834, have made four Reports, and have circulated them largely. From them our chief information must be drawn; for although much discussion has taken place with respect both to the principle of the measure and the mode in which effect has been given to it, no enlarged examination of its working has, with but one exception, been made. This exception is found in the inquiry by the committees of the House of Commons appointed to inquire into certain charges made against the administration of the Commissioners. The evidence of these committees, taken during the two sessions of 1836–37 and 1837–38, and the Report made by the last, though they contain much valuable matter, and especially a very detailed account of the operation of the measure upon the morals and the condition of the labouring poor, are in the main corroborative of the Commissioners' own Report, and in disaffirmance of the charges made against the principle of the act, and the manner of its execution. This evidence, therefore, has also the effect of referring us again for information to the Reports of the Commissioners.

ogress of aniza- n.

It appears from the Reports of the Commissioners, that in four years they have succeeded in uniting 14,811 parishes, which they have arranged in 565 unions; and in placing thirteen parishes under boards of governors, organized and acting in a like manner as in unions. Of these, a hundred and eleven were declared and organized in the first year, two hundred and fifty-two in the second, two hundred and five in the third year, and seventeen in the fourth year. These unions have since become the districts of administration of the act for the registration of births, deaths, and marriages. The presidency of the boards of guardians has been taken by the nobility and leading gentry in their respective unions.[1] Each union is administered by a board of guardians, one guardian at least being elected for each parish or town-land. This board meets in most cases weekly; but many instances exist where, by improved skill in the performance of their functions, and by diminished pauperism, they are enabled to perform their duties efficiently by meeting once a fortnight. Three hundred and twenty-eight unions have workhouses completed and in operation; a hundred and forty-one have workhouses building or in course of alteration. Of the remaining unions, thirty-eight boards of governors have taken no steps for providing themselves with this requisite for good management. Each union is provided with the following officers: A clerk, usually a professional man, auditor, chaplain, medical officers, relieving officers, master and matron of the workhouse, schoolmaster and schoolmistress, and porter.

Amended System.

Savings.

These arrangements involve a large expenditure, but are indispensable to secure the advantages of an improved administration, and of the vastly preponderating saving derivable only from a better system. Before the Poor-Law Amendment Act was passed, the Commission of Inquiry had excited universal attention to the abuses in the poor-laws. The dispersion of their searching inquiries throughout the kingdom; the visits of their assistant Commissioners; above all, the startling picture of abuse contained in the extracts from their information, and the inviting account contained in the same extracts, of the effects, pecuniary and moral, resulting in Cookham, Uley, Southwell, Bingham, Swallowfield, Hatfield, and some few other dispauperised parishes; had produced a wide-spread inclination, a sanguine hope, and in many places a vigorous effort, to reduce the abuses everywhere recognised as now prevailing. The magistracy and clergy especially aided this movement. We find, therefore, the effects of the inquiry developing themselves before the act was passed, and in some measure in the very way in which the act itself was intended to operate. The years 1833 and 1834 thus present a reduction below the previous years, as will be seen in the table at page 375, which is here repeated, and completed up to the present year.

1838	4,123,604	15,423,718	52	6	1,570,897

[2] The numbers given in this column for the years 1801, 1811, 1821, and 1831, are those ascertained at the enumeration of those years; those stated for the intermediate and for subsequent years are computed from the baptisms and burials, and from the rate of increase, as ascertained at each census.

---

shillings; and that women in that neighbourhood could easily earn five shillings a week all the year through. Thus she will have fifteen shillings a week." (*Ibid.* p. 172.)

"At Nuneaton, the solicitor to the parish, Mr Greenaway, stated, that his house looked into the churchyard; that he was in the habit purposely of watching the persons resorting to the church for marriage, and that he could confidently say, that seventeen out of every twenty of the female poor who went there to be married were far advanced in pregnancy." (*Ibid.* 173.)

[1] See List of Officers, &c. in the Fourth Annual Report, Appendix (C), No. 2, pp. 209, *et supra*.

Amended System.

To complete the view here given, the cost per head, calculating the population of the year 1838 as 15,423,718, being at the average rate of increase ascertained by the last census, will give this result, in which, for the purposes of comparison, the portion before given is here repeated.

	s.	d.
In 1800 the payments were......	9s.	1d. each.
1811..	13	1
1821..	10	7
1831..	9	9
1838..	5	4¼

For a connected view of the progress of expenditure, so far as it can now be obtained, previously to the year of inquiry, 1832, during that of the succeeding year, being that of the enactment of the Poor-Law Amendment Act, and thenceforward to the present time, reference may be had to the following table, the details of which for each county may be found at pp. 324, 325, 326, 327, of the Third Annual Report.

Amount of Money expended for the Relief of the Poor in England and Wales in the several years for which Returns have been required by Parliament.

Average of the three years ending at Easter 1748, 1749, and 1750........................		L.689,971
Year ending at Easter 1776........................		1,530,800
Average of the three years ending at Easter 1783, 1784, and 1785........................		2,004,239
Year ending at Easter........................	1803	4,077,891
... ...	1813	6,656,106
... ...	1814	6,294,581
Year ending on the 25th March...........	1815	5,418,846
... ...	1816	5,724,839
... ...	1817	6,910,925
... ...	1818	7,870,801
... ...	1819	7,516,704
... ...	1820	7,330,254
... ...	1821	6,959,251
... ...	1822	6,358,704
... ...	1823	5,772,962
... ...	1824	5,736,900
... ...	1825	5,786,989
... ...	1826	5,928,505
... ...	1827	6,441,089
... ...	1828	6,298,003
... ...	1829	6,332,411
... ...	1830	6,829,042
... ...	1831	6,798,888
... ...	1832	7,036,968
... ...	1833	6,790,799
... ...	1834	6,317,254
... ...	1835	5,526,416
... ...	1836	4,717,629
... ...	1837	4,044,741
... ...	1838	4,123,604

This table shows, that, in comparison with the parochial year ended March 1834, the savings in expenditure were—

1st year......	1835.........	L.790,838, or 13	per cent.
2d year.......	1836.........	1,599,625, or 25	...
3d year.......	1837.........	2,272,513, or 36	...
4th year.......	1838.........	2,193,650, or 35	...

making a total saving during the period the act has been in operation of L.6,856,626, as compared with the year ended March 1834.

The two following statements will show the amount of money expended for the relief and maintenance of the poor during the years ended Easter 1803, and 25th March 1818 and 1837, respectively, specifying the amount, rate per cent., and rate per head, of decrease in 1837, as compared with the years 1803 and 1818 respectively; the former being the year in which the smallest, and the latter the year in which the largest sum of money was expended for the relief of the poor, for which authentic parliamentary returns have been received:

Population in 1801, 8,872,980; expended for relief, &c. of the poor during the year ended Easter 1803, L.4,077, 891.

Population in 1821, 11,978,875; expended for relief, &c. of the poor during the year ended 25th of March 1818, L.7,870,801.

Population in 1831, 13,897,187; expended for relief, &c. of the poor during the year ended 25th of March 1837, L.4,044,741.

From this statement of the population and the expenditure at the periods described, the following results were obtained. The tables show, what is a striking exemplification of the operation of the new system, that the amount expended in 1837 was one per cent. less than that of the lowest year for which any official returns exist, apparently the lowest year in the present century. But when the increase of population is considered, this comparison becomes vastly more favourable to the improved administration. The expenditure in the year 1803, in comparison with the population of 1801, was as nine shillings and twopence per head, whilst that of 1837 was, with comparison of the population of 1831, only five shillings and tenpence.

Amount of decrease in the year ended 25th of March 1837, compared with 1803, L.33,150; ditto compared with 1818, L.3,826,060.

Decrease per cent. in 1837, compared with 1803, one; ditto compared with 1818, forty-nine.

Expenditure per head in 1803, with reference to population in 1801, nine shillings and twopence; ditto in 1818, with reference to population in 1821, thirteen shillings and twopence; ditto in 1837, with reference to population in 1831, five shillings and tenpence.

Decrease per head in 1837, compared with 1803, three shillings and fourpence; ditto compared with 1818, seven shillings and fourpence.

This, however, is still a very unfavourable view of the operations of the new system, as it does not allow for the great increase of population between the years 1831 and 1837. Estimating the population between the years 1801 and 1803 as increasing at the same rate per cent. as the increase shown in the census taken in 1811, and estimating in like manner the increase between 1831 and 1837, in accordance with the rate of increase as shown at the census of 1831, we have these results.

Rate per head in the year 1803..........	8s.	11d.
Ditto in 1837..	5	4
In favour of 1837.........	3s.	7d. per head.

Moral results.

The means of comparison between the state of the pauper and of the labouring population in the two periods preceding and succeeding the passing of the act, are not by any means so abundant as those of making the comparison of expenditure. It is nevertheless clearly apparent, that in proportion as the expenditure is diminished, the number of paupers maintained has diminished; and that the reliance on the rate, the idleness which it rendered possible, and the indulgence which it afforded, must have been on the whole proportionally diminished. We have full evidence that the diminution in enjoyment has not been at the expense of the aged, the infirm, or the impotent. The restrictive rules applied by the Commissioners (see Appendix to their First Report, p. 85) to various classes of able-bodied paupers, with various degrees of strictness, carefully preserved to the aged and impotent the benefits of the relief, such as might have been given them under the old system, but which, as shown by the Commissioners of Inquiry, was refused to them, and lavished on the insolent and reckless of the able-bodied. Now the returns show, that precisely in the places where able-bodied pauperism most prevailed, there, at the same time, the relief of the aged was least cared for; and they equally

Amended System.

show, that with the diminution of relief to the able-bodied, that to the aged and infirm has become more liberal. (See Appendix to the Second Annual Report, p. 309, 311, 416.)[1]

Improved ndustry.

The evidence as to the improvement of the labourer is too abundant to allow us even to refer the reader to all the passages in the Commissioners' Reports; but conclusive evidence will be found in the passages referred to under the title "Labourers" in the index of the Second Annual Report. These show a great improvement in the general conduct of labourers when made dependent upon the good opinion or good will of their employers; a manifest improvement in the labour of workmen when wages were substituted for relief, and, what might be expected, a parallel increased demand for the improved labour. Equally strong is the evidence of the decrease of crime, and particularly of those petty offences, such as poaching, snaring, and the smaller kinds of depredation, for which the former unsteady occupation of the farm-labourer afforded him facilities. The illustration of these subjects will be found most abundant, and in greatest detail, in the evidence given before the Select Committees of the House of Commons in the sessions 1836–37 and 1837–38. There will also be found evidence of the diminution of improvident habits generally; the increase of benefit clubs, and of deposits in savings' banks, though shown here, is made even more manifest by the returns collected and observed upon by Mr Tufnell in the Appendix to the Fourth Annual Report (p. 220–222), extracts from which are here given.

Amended System.

Providence.

"With so many circumstances tending to retard the prosperity of the labouring classes, it is gratifying to have to observe, that, so far as can be collected from statistical documents (and to figures, as being less capable of error, I am always desirous of referring), their welfare seems to have been upon the whole in a state of steady advancement since the enforcement of the regulations of the new poor-law. As one proof of this I beg to refer to the following table, which shows the deposits during the last seven years in the savings' banks in the two counties of Kent and Sussex, from friendly societies, and from the depositors of sums under L.20. I have selected these two classes of depositors, as amongst them, more than in any other class, the labouring population are chiefly to be found.

Date.	In the Kent Savings' Banks.	In the Sussex Savings' Banks.	Observations.

.... 1837	110,156	51,409	

"The three years previous to the passing of the Poor-Law Amendment Act were by no means unprosperous ones as respects those natural circumstances that affect the condition of the labourers. Yet it will be perceived how slowly the

---

[1] Mr Raper, clerk of the Westhampnett Union, gave much valuable evidence on the beneficial working of the amended system before the committee of the House of Commons in session 1836–37, from which we make the following extracts:—

"With reference to the aged and infirm, have you been in the habit of giving them relief out of the house?—Certainly.

"Have you ordered them into the house on any occasions, refusing them relief out of it?—The order to an aged or infirm person to come into the house has been an exception; the general rule has been to give the relief out.

"What was the state of things in that respect before the new poor-law came into operation?—The allowances to the aged and infirm have been, generally speaking, increased since the union.

"With regard to going into the house or not?—I think there have been less aged and infirm ordered into the house since the union than previously." (3165–68.)

In the parish of Graffham, in the same union, the payments made to aged persons under the old law are stated by Mr Sadler to have been as follows:—

"By reference to the poor-book I will describe the former payments; the former allowance to this same couple, who now receive five shillings a week, was two shillings a week; the widow woman who now receives two shillings and sixpence a week used to receive one shilling a week; and the single man who now receives two shillings and sixpence, used to receive two shillings.

"Then in the parish of Graffham the payment to the aged appears to have increased?—Doubled, exactly." (17,503–4.)

The extracts from the evidence of Mr Ellis, Mr Butt, and Mr Ford, each of whom is unfavourable to the regulations of the amended system, all relate to the Petworth Union:—

"How has it (the new law) affected the aged and infirm?—The aged are taken care of now in their own parish, the same as they were before the union.

"Have many of the aged and infirm been removed into the workhouses?—Very few; not more than we had before the union." (349; Mr Ford.)

"Upon the aged and infirm paupers what do you think has been the effect of the act?—I should think that they are full as well off, and perhaps better, than they were before.

"Do they receive out-door relief?—Yes, mostly; and if I might be allowed to say, that is one of the arguments that I make use of when I ask that we may have the discretion with respect to the labourers with large families. We have the discretion with respect to the aged, and therefore have used it, and enabled them to receive that comfort under this poor-law that they had before, or perhaps more." (1490–1.)

"You have stated that you consider the condition of the aged poor to be improved; in what respect?—I hardly stated that they were improved; I said that they were as well off, if not better. In the case of aged persons, we give them the choice whether they will live out at a certain allowance, about two shillings and sixpence a week, or come into the old poor-house. If they have a child to live with, or any other person, they generally take the two shillings and sixpence instead of coming into the poor-house.

"Was not that the condition of the poor before the poor-law came into operation?—Yes, the same.

"Then in what way is their condition improved?—I think that our allowance was rather more than was given by the parishes." (1629–31; Mr Ellis.)

"Have the aged and infirm received the same amount of comforts, or a greater amount of comforts?—Greater; more liberal.

"Has there been any severity exercised towards widows or children, or single women?—Not in our Union; quite the reverse." (2664–5; Mr Butt.)

Amended System.

deposits increased in comparison to what they have done since the passing of the poor-law, and that in 1832 there was a large diminution.

“ The following table, showing the increase of the various classes of depositors in the Tunbridge Wells savings' banks between 1831 and 1837, presents gratifying proof of the greater prevalence of a spirit of providence, especially amongst the poorer classes :—

	In 1836.	In 1837.	Increase per Cent.
Servants	361	483	34
Agricultural labourers	46	137	200
Children	357	388	9
Journeymen and apprentices	39	57	46
Charitable societies	14	26	86
Benefit societies	4	5	25
Small shopkeepers	8	16	100
Small farmers, and others not described.	54	68	26
Total	883	1180	34

“ The increase of forethought in the labourers is perhaps still more strikingly manifested by the increase of members in friendly societies, which are now far more generally established on principles calculated to secure a certain provision in sickness and old age, instead of those injurious institutions, hitherto so prevalent, which seem intended only to minister to the profit of publicans, and which are usually founded on principles that must inevitably cause their dissolution when old age overtakes the members, and consequently when the utility of such societies would be most apparent, and their benefits most needed.

“ I have received the numbers that have annually belonged to three benefit societies, and these I give below. The first is a friendly society in the county of Sussex.

“ Number of members in 1831, 84; in 1832, 64; in 1833, 56; in 1834, 48; in 1835, 49; in 1836, 64; in 1837, 98.

“ The following are the returns from two Kentish friendly societies :—

“ Number of members in 1832, 378; in 1833, 363; in 1834, 356; in 1835, 353; in 1836, 420; in 1837, 478.

“Number of members in 1831, 461; in 1832, 477; in 1833, 519; in 1834, 533; in 1835, 609; in 1836, 611; in 1837, 770.

“ It will be perceived that these figures indicate either a very slow increase or an actual diminution previous to the passing of the new law, and a rapid advancement since.

“ These contrasts, however, are far less favourable to the present system than they would appear, had not the failure of the crops and the hardness of the seasons during the last year and a half pressed with peculiar severity on the labouring classes of this district. Every natural circumstance seems to have combined to test to the utmost the soundness of the principles of the poor-laws, and put their efficacy to the proof. In the two counties of Kent and Sussex referred to in the above table of the deposits in savings' banks, *upwards of a million of money has been subtracted from the poor-rates since the regulations of the Poor-Law Amendment Act came into operation*; and if, in the face of this large reduction, and of many adverse circumstances, we are enabled to refer, not to obscure deductions and conjectures, but to the unimpeachable testimony of facts like the above, are we not entitled to assume that the effect of the measure has not been hurtful to the interests of the labourers or of society in general, and that the apprehensions entertained of it are not justified by the result?”

The most impressive proof that strong motives must have been given to the able-bodied to resume the habits of honest and independent industry, may be found in a return of the operation of the law in the county of Sussex, a county in which able-bodied pauperism appeared to have had the firmest root, and the circumstances of which county afforded, at the passing of the act, the least hope of eradicating this evil. It will be seen in the table, that almost in proportion as the rate of savings in the year are large, is the effect most strikingly shown upon the able-bodied paupers.

“ *Summary of what Sussex Pauperism was under the Old System, and what it is, after little more than One Year's experiment, under the New.*

Marriage. One of the moral effects most to be desired was the rendering marriage no longer a consideration of policy as regarded the chances of the couple to relief, or as a means of obtaining an annuity with a family of ante-nuptial children; an effect sought by the recommendations of the Commissioners and the enactments described, and one which appears to have been abundantly realised in the operation of the measure. Dr Kay, assistant poor-law commissioner, in his examination before the Committee of the House of Commons in the last session, gave some valuable evidence relative to the decrease in the number of marriages in the counties of Norfolk and Suffolk, the counties under his superintendence, from which we have made some extracts.

"Have you any return relative to marriages which have taken place in Norfolk and Suffolk?—Last spring I instructed the relieving officers of a great number of unions to apply for returns of the marriages which occurred in the parishes in their districts in the years 1833, 1834, 1835, and 1836. A considerable difficulty was experienced in procuring those returns. Where they were procured they were given by the clergymen of the parishes very kindly, as a favour to the relieving officers; but they did not comprise, in consequence of certain difficulties which were experienced, every parish in every officer's district, but only certain of the parishes; but in every case in which the return was obtained from any parishes, it included all those years.

"From the return do you find that the number of marriages has increased or decreased in the period?—I find in this return that the marriages in the year 1833, in the districts to which it relates, were 762; in 1834 they were 771; in 1835, 663; and in 1836, 549; which I believe may be taken as evidence that there has been a considerable diminution of improvident marriages in these districts."

Bastardy. Unfortunately the question of pauper-marriage was too much connected with the operation of the law of bastardy (marriages sometimes brought about by the bribe of the allowance to a family of such children, sometimes by the threat of the jail directed against the man accused of being the father) to allow the effects of the law in diminishing marriages and in diminishing bastardy to be separated or clearly distinguished; but the direct operation of the law in checking unchastity will be seen in the extracts from the Commissioners' Second Annual Report, as inserted below.[1]

Litigation. An important indication of the improved working of the law, proving also an increased cordiality and recognition of common interests between parishes, and showing still more incontestably the benefit of the improvements in the settlement laws, is to be found in the rapid decrease of law-expenses. The sums expended in law-charges and the removal of paupers amounted in the years ended 25th March 1834 to L.258,604, in 1835 to L.202,527, in 1836 to L.172,482, in 1837 to L.126,951, and in 1838 to L.93,982.

This, however, does by no means give a sufficiently favourable view of the effect of the law; for as the amount stated includes all law-expenses, it comprises the expenditure, which has since the passing of the act been very large, in the preparation and execution of contracts, and more particularly of the conveyancing expenses connected with the purchase and hire of lands for workhouses, and with the sales of parish property, which have taken place to a large extent, but which cannot be repeated.

Prospects. It has often been asserted that the diminished cost and improved administration were owing, not so much to the enactment of the Poor-Law Amendment Act, and the new organization introduced by it, as to other general causes; a general improvement in intelligence being sometimes assigned, the increase of certain modes of employment of the people at other times, and innumerable other causes, according to the views of the person offering the explanation. The Fourth Report of the Commissioners affords a very convincing instance of the fact, that where the improved organization has not been effected, all the causes which formerly operated to render the administration stationary, or to make it retrograde, still operate with full effect. Birmingham and Aston are adjoining parishes, with populations of the same habits, and equally participating in every element of prosperity or decline. The year 1837 severely tried the operation of the act. A great failure in many branches of trade and commerce, and two severe winters, had contributed to render the distress of the poor more urgent and more general than at any period since the passing of the act. The high price of provisions during a very large part of the period enhanced these effects. The result has been, that although on the entire operations of the last year every reason appears for entertaining the belief that the improvements in the administration had not been less progressive than in preceding years, the saving in money is, upon the whole, very little greater than that of the year ending March 1837. Birmingham has not yet been placed under the control of the Commissioners' regulations. Aston has been placed under a board of guardians, and is governed under the Commissioners' regulations. It is difficult to suppose that Birmingham has not had its full share of any advantage derivable from increased intelligence or increased prosperity; at all events, it is difficult to suppose that Aston, usually regarded as a part of Birmingham, can have the advantage of any such general influence, and Birmingham be deprived of it. The account shows that, under the trial of circumstances to which each has been equally subjected, the parish of Birmingham has been driven to an increased expenditure of forty-one per cent., while the parish of Aston has successfully withstood the operation of the like circumstances, and has effected a diminution upon its previous expenditure of thirty-five per cent. The comparison, the whole of the details of which are given in the Commissioners' Fourth Annual Report, pp. 362–64, stands thus:—

---

[1] "The Rev. Thomas Pitman, minister of Eastbourne, says, 'Among the labouring classes there is a decided and progressive alteration. Even the farmers themselves have observed to me, that there is in the general conduct of the agricultural labourers a civility of manner, and attention to their masters' wishes, which of late years has been little perceptible. Perhaps the most marked difference in the lower orders, observable by us as clergymen, is the almost total cessation of early and improvident marriages. I should not forget also to mention, that, as far as I can form a judgment, there is also a decided improvement in the marriages that do take place. The altar is not now, as heretofore, disgraced by the appearance of a woman, to take upon her the solemn obligation of matrimony, in the last stage of pregnancy; a fact which, I think, goes far to show, that the morals of the people are undergoing a change for the better, and promises that ere long we may hope for all that domestic happiness among our poorer neighbours which results from a match of pure affection, in the place of all that wretchedness, discord, and misery which are the too sure produce of a marriage commenced in sin, and fostered only by a hope of procuring a means from the parish of carrying on from time to time sinful indulgences.'

"Reverend John Austin, minister of Pulborough, states that 'We now begin to look for moral and religious improvement, as the hard-working men engaged in industry are become civil and attentive to their masters. Only two marriages have been solemnized since December last, the yearly average being fifteen; and only one bastard has been christened between July 12, 1835, and May 17, 1836. (The population of this parish is 1976, according to the census of 1831.)'

"It is satisfactory to us to observe, that the practice, which was at one time almost universal, of dealing with the mothers of bastard children differently from other paupers, is rapidly giving way; and the sounder course of giving them relief only according to the measure and character of their wants is more generally adopted.

"The information which we have received on the subject of the clauses in the new act, with relation to bastardy, is confirmatory of the facts and conclusions stated upon the subject in our last Annual Report. From the returns which we have received, it appears that the whole number of bastards chargeable to the parishes of England and Wales was, in the year 1835, 71,298; the number chargeable in the year 1836 was 61,826; being a decrease of 9472, or of thirteen per cent.

"But the progressive operation of the bill appears in the numbers affiliated during the two years, which numbers were, in 1835, 12,381; in 1836, 7686; being a decrease of 4695, or of thirty-eight per cent.

"We endeavoured to obtain an account of the numbers born during those years chiefly, as shown in the baptismal registers; but our respondents declare that these returns are extremely imperfect, and are so much at variance with other testimony, that no reliance can be placed upon them for accuracy. In some parishes very many of the bastard children are never baptized; and in many other parishes, where they have not been accustomed to baptize them before the passing of the act, children have been baptized subsequently, in consequence of the fact of a woman being known to have had a bastard not rendering her liable to the interference of the parish-officer where she does not claim relief.

"The evidence of midwives and parish-officers, and other witnesses, speaking upon their own knowledge of their respective parishes, would prove that the diminution of the number of births was considerable.

"The number returned as born in the year 1835, was 17,036; and in the year ended 25th March 1836, was 17,578. This variation between the two years is attributed to the more full registration in the last year.

"According to the population returns, the number of bastards born in the year 1831 was 20,039, which, if allowance were made for the increase of population since that year, would show a decrease of between 4000 and 5000 born in the last year." (Second Annual Report, pp. 17, 18, 19.)

A better proof can scarcely be found of the efficiency of the amendments to protect the country against a return to the state of things from which the law has so recently extricated us. (A. A. A. A. A.)

POORNAH, a river of Hindustan, which rises in the Injardy Hills, whence it flows westward through Berar, and falls into the Tuptee about twenty miles below Boorhanpoor.

POORPOOROO, a small island in the Eastern Seas, near the north-eastern coast of Borneo. Long. 117. 54. E. Lat. 6. 18. N.

POORUNDER, a celebrated town and fortress of Hindustan, in the province of Bejapore. It belonged till lately to the peshwa. It was in this fortress that the widow of Narrain Row took refuge after the murder of her husband, and where she brought forth her posthumous child, who succeeded to the dignity of peshwa. It is seventeen miles from Poonah. Long. 74. 5. E. Lat. 18. 16. N.

POORWAH, a town of Hindustan, in the nabob of Oude's territories, twenty-eight miles south-south-west from Lucknow. Long. 80. 44. E. Lat. 20. 28. N.

POOSHKUR, or PHOKUR, a town of Hindustan, in the province of Ajmeer, and situated on the shore of a romantic lake. It contains a remarkable temple dedicated to Brahma, with an image that has four heads and as many arms, besides other temples dedicated to Vishnu and Seva. The town contains about 700 houses, the inhabitants of which are mostly Brahmins, who depend entirely on charity for support. Here is also a mosque, built by a Mahommedan nobleman, tutor to the Emperor Akbar. It is four miles from Ajmeer.

POOTELLAM, a town of Hindustan, on the western coast of Ceylon, celebrated for an extensive manufactory of sea-salt, which formerly supplied Candy and the interior. Long. 79. 51. E. Lat. 8. 5. N.

POOTI, a river on the east coast of Sumatra, which falls into the Sea of Java. Long. 105. 45. E. Lat. 4. 38. S.

POPAYAN, a province included in the republic of New Grenada, in South America. It is situated in the department of Cauca, and is bounded on the south by Pasto, on the west by Buenaventura and Choco, on the east by Neiva and Bogota, and on the north by Antioquia. This province is somewhat rugged and mountainous, but withal one of the richest and finest districts in all America. The banks of the river Cauca appear to present the greatest indications of opulence, the soil being deep, and the pasturages rich and fertile. Even the muleteers, proud of being whites, are ashamed to go on foot, so that it is difficult to distinguish the poor from the rich. This prosperity and opulence are to be ascribed to a fertile soil, and to abundant gold mines, though they are unskilfully worked.

Popayan, the capital of the province, is finely situated on the banks of the Cauca, at the foot of the volcanic mountain of Purace. Mollien, who visited this city, speaks highly in praise of its site. "It is said," he remarks, "that the position of Popayan seems to have been created by the imagination of poets; and in fact it is difficult to find one more beautiful. It was selected by Benalcazar, who is less known than either Pizzaro, Cortes, or Quesada, but deserves to be more celebrated, as he was the founder of many towns, all delightfully situated." It is handsomely built, and its elevation above the sea, which is 5750 feet, renders the climate mild and agreeable. This city suffered greatly, as did the whole province, during the war of independence; and in the year 1827 it was almost entirely destroyed by an earthquake, which was accompanied by an eruption of the volcano of Purace, and an overflow of the Cauca. Before this calamity, the inhabitants were estimated at 20,000.

Amongst the other towns of this province may be mentioned that of Purace, which is agreeably situated above the valley of Popayan. It is a neat place, each house being built in the midst of an enclosure. Caly is another prettily-built town, situated on the declivity of the western cordilleras. Considerably further down the Cauca, almost at the extremity of the great plain, is situated Carthago. It stands near the point where the two cordilleras approach, leaving only a narrow passage for the river, and is the entrepôt for the goods destined for Santa Fe, which arrive by the Quindiu, and those for the Antilles or the ocean, which come by way of Novita, situated near the Rio San Juan. The population of the whole province of Popayan is estimated at about 107,000.

POPE, a name which comes from the Greek word Παπα, and signifies *Father*. In the East this appellation is given to all Christian priests, and in the West bishops were called by it in ancient times; but for many centuries it has been appropriated to the bishop of Rome, whom the Roman Catholics look upon as the common Father of all Christians.

Within the last two or three centuries, much has been said and written, and many warm disputes have been carried on, concerning the Pope, and the power belonging to him. After describing the manner of his election, we shall here, without entering into controversy, lay down distinctly, from the best authority, what the Roman Catholics really believe concerning the Pope; and we shall give some other particulars relating to this subject which seem to deserve notice, and which are not generally known in this country.

All those in communion with the see of Rome unanimously hold that our Saviour Jesus Christ constituted St Peter the apostle chief pastor under himself, to watch over his whole flock here upon earth, and to preserve the unity of the church, at the same time giving him the power requisite for these ends. They also believe that our Saviour ordained that St Peter should have successors with the like authority and power, to the end of time. Now, as they allege that St Peter resided for many years at Rome, and there suffered martyrdom, they consider the bishops of Rome as his successors in the dignity and office of the universal pastor of the whole Catholic Church.

There have been some varieties in the manner of choosing the bishop of Rome in different ages, as alterations may be made in discipline; but still the clergy of Rome have always had the chief part in the election; and that clergy is now represented by, or in some manner consists of, the cardinals, who have for several centuries been the sole electors of the Pope.

These cardinals, or principal persons of the church of Rome, are seventy in number, when the sacred college, as it is called, is complete. Of these, six are cardinal bishops, viz. the bishops of Ostia, Porto, Albano, Sabino, Tusculum or Frascati, and Præneste or Palestrina, which are the six suburbicarian churches; fifty are cardinal priests, who have all titles from parish churches in Rome; and fourteen are cardinal deacons, who have their titles from churches in Rome of less note, called *diaconias* or deaconries. These cardinals are created by the Pope when there happen to be vacancies. Sometimes he names one or two only at a time; but commonly he defers the promotion until there be ten or twelves vacancies or more; and then at every second such promotion, the emperor, the kings of Spain and France, and of Great Britain when Catholic, are allowed to present one each, to be made cardinal, whom the Pope always admits if there be not some very great and evident objection. These cardinals are commonly promoted from amongst such clergymen as have borne offices in the Roman court; some are assumed from religious orders; and eminent ecclesiastics of other countries are likewise often honoured with this dignity. Sons of sovereign princes have frequently been members of the sacred college. Their distinctive dress is scarlet, to signify that they ought to be ready to shed their blood for the faith and the church, when the defence and honour of either require it. They wear a scarlet cap and hat. The cap is given to them by the Pope if they are at Rome, and is sent to them if they are absent; but the hat is never given but by the Pope's own hand. These cardinals form the Pope's standing council or consistory for the management of the public affairs of church and state. They are divided into different congregations for the more easy despatch of business; and some of them hold the principal offices in the pontifical court, as that of cardinal-vicar, penitentiary, chancellor, camerlingo or chamberlain, prefect of the signature of justice, prefect of memorials, and secretary of state. They have the title of *eminence* and *most eminent* given them. But here we consider them principally as the persons intrusted with the choice of the Pope.

On the demise of a Pope, his pontifical seal is immediately broken by the chamberlain, and all public business is interrupted that can be delayed. Messengers are despatched to all the Catholic sovereigns to acquaint them of the event, that they may take what measures they think proper, and that the cardinals in their dominions, if any there be, may hasten to the future election if they choose to attend; whilst the whole attention of the sacred college is turned to the preservation of tranquillity in the city and state, and to the necessary preparations for the future election. The cardinal chamberlain, during the vacancy of the holy see, possesses great authority; he coins money with his own arms on it, lodges in the Pope's apartments, and is attended by body-guards. He, and the first cardinal bishop, the first cardinal priest, and the first cardinal deacon, have, during that time, the government almost entirely in their hands. The body of the deceased Pope is carried to St Peter's, where funeral service is performed for him with great pomp during nine days, and the cardinals attend there every morning. In the mean time, all necessary preparations for the election are made; and the place where they assemble for that purpose, which is called the conclave, is fitted up in that part of the Vatican palace which is nearest St Peter's church, as this has long been thought the most convenient situation. Here is formed by partitions of wood a number of cells or chambers equal to the number of cardinals, with a small distance between every two, and a broad gallery before them. A number is put upon every cell, and small papers with corresponding numbers are put into a box. Every cardinal, or some one for him, draws out one of these papers, which determines in what cell he is to lodge. The cells are lined with cloth; and there is a part of each one separated for the conclavists or attendants, of whom two are allowed to each cardinal, and three to cardinal princes. They are persons of some rank, and generally of great confidence; but they must carry in their master's meals, serve him at table, and perform all the offices of a menial servant. Two physicians, two surgeons, an apothecary, and some other necessary officers, are chosen for the conclave by the cardinals.

On the tenth day after the Pope's death, the cardinals who are then at Rome, and in a competent state of health, meet in the chapel of St Peter's, which is called the Gregorian Chapel, where a sermon on the choice of a Pope is preached to them, and mass is said for invoking the grace of the Holy Ghost. Then the cardinals proceed to the conclave in procession two by two, and take up their abode. When all is properly settled, the conclave is shut up, having boxed wheels or places of communication in convenient quarters; and there are also strong guards placed all around. When any foreign cardinal arrives after the inclosure, the conclave is opened for his admission. In the beginning every cardinal signs a paper, containing an obligation, that if he shall be raised to the papal chair he will not alienate any part of the pontifical dominion; that he will not be prodigal to his relations; and such other stipulations as may have been settled in former times or framed for the occasion.

We come now to the election itself; and that this may be effectual, two thirds of the cardinals present must vote for the same person. As this is often not easily obtained, they sometimes remain whole months in the conclave. They meet in the chapel twice every day for giving their votes; and the election may be effected by scrutiny, accession, or acclamation. Scrutiny is the ordinary method, and consists in this: Every cardinal writes his own name on the inner part of a piece of paper, and this is folded up and sealed. On a second fold of the same paper a conclavist writes the name of the person for whom his master votes. This, according to the practice observed for some centuries, must be one of the sacred college. On the outer side of the paper is written a sentence at random, which the voter must well remember. Every cardinal, on entering into the chapel, goes to the altar and puts his paper into a large chalice.

When all are convened, two cardinals number the votes; and if they are more or less than the number of cardinals present, the voting must be repeated. When that is not the case, the cardinal appointed for the purpose reads the outer sentence, and the name of the cardinal under it, so that each voter hearing his own sentence and the name joined with it, knows that there is no mistake. The names of all the cardinals that are voted for are taken down in writing, with the number of votes for each; and when it appears that any has two thirds of the number present in his favour the election is over; but when this does not happen, the voting papers are all immediately burned without opening up the inner part. When several trials of coming to a conclusion by this method of scrutiny have been made in vain, recourse is sometimes had to what is called accession. By it, when a cardinal perceives that one or very few votes are wanting to any one for whom he had not voted at that time, he may say that he accedes to the one who has nearly the number of votes requisite; and if his one vote suffices to make up the two thirds, or if he is followed by a sufficient number of new voters for the said cardinal, the election is accomplished. Lastly, a Pope is sometimes elected by acclamation; that is, when a cardinal, being pretty sure that he will be joined by a sufficient number, cries out in the open chapel, that such a one shall be Pope. If he is supported properly, the election becomes unanimous; those who would perhaps oppose it foreseeing that their opposition would be fruitless, and rather hurtful to themselves. It is to be observed, that the emperor of Germany and the kings of France and Spain claimed a right of excluding one cardinal from being Pope at every election. Hence, when the ambassador at Rome of any of these sovereigns perceived that any cardinal disagreeable to his master was likely to be made Pope, he demanded an audience of the conclave, was admitted, and there declared his master's will, which was always attended to for the common good. But each of those sovereigns was thus allowed to exclude only one at a time; and they unwillingly and seldom put this right in execution.

When a Pope is chosen in any of the three above-mentioned ways, the election is immediately announced from the balcony in the front of St Peter's; homage is paid to the new pontiff; and couriers are sent off with the news to all parts of Christendom. The Pope appoints a day for his coronation at St Peter's, and for his taking possession of the patriarchal church of St John Lateran; all which is performed with great solemnity. He is addressed by the title of Holiness, and Most Holy Father.

Let us now proceed to state what authority Roman Catholics attribute to the Pope thus chosen. They believe, then, that the bishop of Rome is, under Christ, supreme pastor of the whole church; and as such, is not only the first bishop in order and dignity, but has also a power and jurisdiction over all Christians, to preserve unity and purity of faith and moral doctrine, and to maintain order and regularity in all churches. Wherefore they hold, that when the Pope understands that any error has been broached against faith or manners, or that any considerable difference on such subjects has arisen in any part of Christendom, it belongs to him, after due deliberation and consultation, to issue out his pastoral decree, condemning the error, clearing up the doubt, and declaring what has been handed down, and what is to be believed. Some Catholic divines are of opinion that the Pope cannot err when he thus addresses himself to all the faithful on matters of doctrine. They well know, that as a private doctor he may fall into mistakes as well as any other man; but they think, that when he teaches the whole church, Providence must preserve him from error; and they apprehend, that this may be deduced from the promises of Christ to St Peter, and from the writings of the ancient fathers. It is to be observed, however, that this infallibility of the Pope, even when he pronounces in the most solemn manner, is only an opinion, and not an article of Roman Catholic faith. Wherefore, when he sends forth doctrinal decrees, the other bishops, who are also guardians of the faith in an inferior degree, may, with due respect, examine these decrees; and if they find them agree with what has always been taught, they either formally signify their acceptance, or they tacitly acquiesce, which, considering their duty, is equivalent to a formal approbation. When the acceptation of the generality of the bishops has been obtained, either immediately or after some mutual correspondence and explanation, the decrees of the Pope thus accepted come to be the sentence of the whole church, and are believed to be beyond the possibility of error.

Sometimes it happens that the disputes and differences may be so great and intricate, that, to the end it may be seen more clearly what has really been delivered down, and to give all possible satisfaction, it may appear proper to convene all the bishops who can conveniently attend, at one place, to learn from them more distinctly what has been taught and held in their respective churches. Roman Catholics believe that it belongs to the Pope to call such general councils, and to preside in them in person or by his legates. They likewise hold, that when the Pope has approved the decrees of such councils concerning faith or manners, such decrees become final, and must be received as such by all Catholics. In all this they believe that the particular assistance of the Holy Ghost is with the pastors of the church, and that therefore "the gates of hell shall never prevail against her."

The see of Rome, according to the Roman Catholics, is the centre of Catholic unity. All their bishops communicate with the Pope, and by his means with one another, and so form one body. However distant their particular churches may be, they all meet at Rome either in person or by their delegates, or at least by their letters; and, according to the discipline of the latter ages, though they are presented to the Pope for their office from their respective countries, yet from him they must receive their bulls of consecration before they can take possession of their sees.

In matters of ecclesiastical discipline, the Pope, as chief pastor, not only must take care that the canons actually in force be observed in all churches, but he may also make new canons and regulations when he sees it necessary or expedient for the spiritual benefit of the faithful, according to times and circumstances. But in doing this he must not infringe the established rights or customs to the injury of any person; which if, through mistake or wrong information, he should ever do, the persons who think themselves aggrieved may remonstrate with respect, and sue for redress. He may establish new episcopal sees where there have been none before, and he may alter the limits of former dioceses; but in such alterations he always of course consults the temporal sovereign, if in communion with him. He sends pastors to preach the gospel to all countries where the Catholic religion is not by law established; and to him appeals may be made from all parts of Christendom in ecclesiastical causes of importance.

The Pope may dispense with the observation of ecclesiastical canons when there are just reasons for it; he may also dispense with vows when they are made with the express or tacit condition[1] that he really may dispense with them; he may also on some occasions declare that obligations have really ceased when that is truly the case, from a great alteration of circumstances. But he can never grant any dispensation to the injury of any third person, and can never allow any one to do what is unjust, or to say what he knows to be false, whatever advantage might be expected to accrue from it.

The reader who wishes to learn what may be urged for and against the supremacy of the Pope, and who is fitted by his knowledge of ecclesiastical history to understand the nature of the question at issue, may consult, on the one hand, the works of Bellarmine, with the chapter on Supremacy in Milner's Letters to a Prebendary; and on the other, Barrow's treatise on the Pope's Supremacy, together with Chillingworth's Religion of Protestants.

---

[1] Any other man may unquestionably do the same when they are made with that express condition.

POPE.

POPE, ALEXANDER, the most brilliant of all wits who have at any period applied themselves to the poetic treatment of human manners, to the selecting from the play of human character what is picturesque, or the arresting what is fugitive, was born in the city of London on the 21st[1] day of May in the memorable year 1688; about six months, therefore, before the landing of the Prince of Orange, and the opening of that great revolution which gave the final ratification to all previous revolutions of that tempestuous century. By the "city" of London the reader is to understand us as speaking with technical accuracy of that district which lies within the ancient walls and the jurisdiction of the lord mayor. The parents of Pope, there is good reason to think, were of "gentle blood," which is the expression of the poet himself when describing them in verse. His mother was so undoubtedly; and her illustrious son, in speaking of her to Lord Harvey, at a time when any exaggeration was open to an easy refutation, and writing in a spirit most likely to provoke it, does not scruple to say, with a tone of dignified haughtiness not unbecoming the situation of a filial champion on behalf of an insulted mother, that by birth and descent she was not below that young lady (one of the two beautiful Miss Lepels) whom his lordship had selected from all the choir of court beauties as the future mother of his children. Of Pope's extraction and immediate lineage for a space of two generations we know enough: beyond that we know little: of this little a part is dubious; and what we are disposed to receive as *not* dubious, rests chiefly on his own authority. In the prologue to his Satires, having occasion to notice the lampooners of the times, who had represented his father as "a mechanic, a hatter, a farmer, nay a bankrupt," he feels himself called upon to state the truth about his parents; and naturally much more so at a time when the low scurrilities of these obscure libellers had been adopted, accredited, and diffused by persons so distinguished in all points of personal accomplishment and rank as Lady Mary Wortley Montagu and Lord Harvey: "*hard as thy heart*," was one of the lines in their joint pasquinade, "*hard as thy heart, and as thy birth obscure*." Accordingly he makes the following formal statement: "Mr Pope's father was of a gentleman's family in Oxfordshire, the head of which was the Earl of Downe. His mother was the daughter of William Turner, Esq. of York: she had three brothers, one of whom was killed; another died in the service of King Charles [meaning Charles I.]; the eldest, following his fortunes, and becoming a general officer in Spain, left *her* what estate remained after the sequestrations and forfeitures of her family." The sequestrations here spoken of were those inflicted by the commissioners for the parliament; and usually they levied a fifth, or even two fifths, according to the apparent delinquency of the parties. But in such cases two great differences arose in the treatment of the royalists; first, that the report was coloured according to the interest which a man possessed, or other private means for biassing the commissioners; secondly, that often, when money could not be raised on mortgage to meet the sequestration, it became necessary to sell a family estate suddenly, and therefore in those times at great loss; so that a nominal fifth might be depressed by favour to a tenth, or raised by the necessity of selling to a half. And hence might arise the small dowry of Mrs Pope, notwithstanding the family estate in Yorkshire had centred in her person. But, by the way, we see from the fact of the eldest brother having sought service in Spain, that Mrs Pope was a Papist; not, like her husband, by conversion, but by hereditary faith. This account, as publicly thrown out in the way of challenge by Pope, was, however, sneered at by a certain Mr Pottinger of those days, who, together with his absurd name, has been safely transmitted to posterity in connection with this single feat of having contradicted Alexander Pope. We read in a diary published

---

[1] Dr Johnson, however, and Joseph Warton, for reasons not stated, have placed his birth on the 22d. To this statement, as opposed to that which comes from the personal friends of Pope, little attention is due. Ruffhead and Spence, upon such questions, must always be of higher authority than Johnson and Warton, and *a fortiori* than Bowles. But it ought not to be concealed, though hitherto unnoticed by any person, that some doubt after all remains whether *any* of the biographers is right. An anonymous writer, contemporary with Pope, and evidently familiar with his personal history, declares that he was born on the 8th of June; and he connects it with an event that, having a public and a partisan interest (the birth of that Prince of Wales who was known twenty-seven years afterwards as the Pretender), would serve to check his own recollections, and give them a collateral voucher. It is true he wrote for an ill-natured purpose; but no purpose whatever could have been promoted by falsifying this particular date. What is still more noticeable, however, Pope himself puts a most emphatic negative upon all these statements. In a pathetic letter to a friend, when his attention could not have been wandering, for he is expressly insisting upon a sentiment which will find an echo in many a human heart, viz. that a birthday, though from habit usually celebrated as a festal day, too often is secretly a memorial of disappointment, and an anniversary of sorrowful meaning, he speaks of the very day on which he is then writing as his own birthday; and indeed what else could give any propriety to the passage? Now the date of this letter is January 1, 1733. Surely Pope knew his own birthday better than those who have adopted a random rumour without investigation.

But, whilst we are upon this subject, we must caution the readers of Pope against too much reliance upon the chronological accuracy of his editors. *All* are scandalously careless; and generally they are faithless. Many allusions are left unnoticed, which a very little research would have illustrated; many facts are omitted, even yet recoverable, which are essential to the just appreciation of Pope's satirical blows; and dates are constantly mis-stated. Mr Roscoe is the most careful of Pope's editors; but even he is often wrong. For instance, he has taken the trouble to write a note upon Pope's humorous report to Lord Burlington of his Oxford journey on horseback with Lintot; and this note involves a sheer impossibility. The letter is undated, except as to the month; and Mr Roscoe directs the reader to supply 1714 as the true date, which is a gross anachronism. For a ludicrous anecdote is there put into Lintot's mouth, representing some angry critic, who had been turning over Pope's Homer, with frequent *pshaws*, as having been propitiated, by Mr Lintot's dinner, into a gentler feeling towards Pope, and, finally, by the mere effect of good cheer, without an effort on the publisher's part, as coming to a confession, that what he ate and what he had been reading were equally excellent. But in the year 1714 *no part* of Pope's Homer was printed; June 1715 was the month in which even the subscribers first received the four earliest books of the Iliad; and the public generally not until July. This we notice by way of specimen; in itself, or as an error of mere negligence, it would be of little importance; but it is a case to which Mr Roscoe has expressly applied his own conjectural skill, and solicited the attention of his reader. We may judge therefore of his accuracy in other cases which he did not think worthy of examination.

There is another instance, presenting itself in every page, of ignorance concurring with laziness, on the part of all Pope's editors, and with the effect not so properly of misleading as of perplexing the general reader. Until Lord Macclesfield's bill for altering the style in the very middle of the eighteenth century, six years therefore after the death of Pope, there was a custom, arising from the collision between the civil and ecclesiastical year, of dating the whole period that lies between December 31st and March 25th (both days *exclusively*) as belonging indifferently to the past or the current year. This peculiarity had nothing to do with the old and new style, but was, we believe, redressed by the same act of parliament. Now in Pope's time it was absolutely necessary that a man by the Microcosm, "*Met a large hat, with a man under it.*" And so, here, we cannot so properly say that Mr Pottinger brings down the contradiction to our times, as that the contradiction brings down Mr Pottinger. "Cousin Pope," said Pottinger, "had made himself out a fine pedigree, but he wondered where he got it:" and he then goes on to plead in abatement of Pope's pretensions, "that an old maiden aunt, equally related" (that is, standing in the same relation to himself and to the poet), "a great genealogist, who was always talking of her family, never mentioned this circumstance." And again we are told, from another quarter, that the Earl of Guildford, after express investigation of this matter, "was sure that," amongst the descendants of the Earls of Downe, "there was none of the name of Pope." How it was that Lord Guildford came to have any connection with the affair, is not stated by the biographers of Pope; but we have ascertained that, by marriage with a female descendant from the Earls of Downe, he had come into possession of their English estates.

Finally, though it is rather for the honour of the Earls of Downe than of Pope to make out the connection, we must observe that Lord Guildford's testimony, *if ever given at all*, is simply negative; he had found no proofs of the connection, but he had not found any proofs to destroy it; whilst, on the other hand, it ought to be mentioned, though unaccountably overlooked by all previous biographers, that one of Pope's anonymous enemies, who hated him personally, but was apparently master of his family history, and too honourable to belie his own convictions, expressly affirms of his own authority, and without reference to any claim put forward by Pope, that he was descended from a junior branch of the Downe family: which testimony has a double value; first, as corroborating the probability of Pope's statement viewed in the light of a fact; and, secondly, as corroborating that same statement viewed in the light of a current story, true or false, and not as a disingenuous fiction put forward by Pope to confute Lord Harvey.

It is probable to us, that the Popes, who had been originally transplanted from England to Ireland, had in the person of some cadet been re-transplanted to England; and that having in that way been disconnected from all personal recognition, and all local memorials of the capital house, by this sort of *postliminium*, the junior branch had ceased to cherish the honour of a descent which was now divided from all direct advantage. At all events, the researches of Pope's biographers have not been able to trace him farther back in the paternal line than to his grandfather; and he (which is odd enough, considering the popery of his descendants) was a clergyman of the established church in Hampshire. This grandfather had two sons: of the eldest nothing is recorded beyond the three facts, that he went to Oxford, that he died there, and that he spent the family estate.[1] The younger son, whose name was Alexander, had been sent when young, in some commercial character, to Lisbon;[2] and there it was, in that centre of bigotry, that he became a sincere and most disinterested Catholic. He returned to England; married a Catholic young widow; and became the father of a second Alexander Pope, *ultra Sauromatas notus et Antipodes.*

By his own account to Spence, Pope learned "very early to read;" and writing he taught himself "by copying from printed books;" all which seems to argue, that, as an only child, with an indolent father and a most indulgent mother, he was not molested with much schooling in his infancy. Only one adventure is recorded of his childhood, viz. that he was attacked by a cow, thrown down, and wounded in the throat.

Pope escaped this disagreeable kind of vaccination with-

---

should use this double date, because else he was liable to be seriously misunderstood. For instance, it was then always said that Charles I. had suffered on the 30th of January $164\frac{8}{9}$; and why? Because, had the historian fixed the date to what it really was, 1649, in that case all those (a very numerous class) who supposed the year 1649 to commence on Ladyday, er March 25, would have understood him to mean that this event happened in what we *now* call 1650, for not until 1650 was there any January which *they* would have acknowledged as belonging to 1649, since *they* added to the year 1648 all the days from January 1 to March 24. On the other hand, if he had said simply that Charles suffered in 1648, he would have been truly understood by the class we have just mentioned; but by another class, who began the year from the 1st of January, he would have been understood to mean what we *now* mean by the year 1648. There would have been a sheer difference, not of one, as the reader might think at first sight, but of *two* entire years in the chronology of the two parties; which difference, and all possibility of doubt, is met and remedied by the fractional date $\frac{1648}{1649}$; for that date says in effect it was 1648 to you who do not open the new year till Ladyday; it was 1649 to you who open it from January 1. Thus much to explain the real sense of the case; and it follows from this explanation, that no part of the year ever *can* have the fractional or double date except the interval from January 1 to March 24 inclusively. And hence arises a practical inference, viz. that the very same reason, and no other, which formerly enjoined the use of the compound or fractional date, viz. the prevention of a capital ambiguity or dilemma, now enjoins its omission. For in our day, when the double opening of the year is abolished, what sense is there in perplexing a reader by using a fraction which offers him a choice without directing him how to choose. In fact, it is the *denominator* of the fraction, if one may so style the lower figure, which expresses to a modern eye the true year. Yet the editors of Pope, as well as many other writers, have confused their readers by this double date; and why? Simply because they were confused themselves. Many errors in literature of large extent have arisen from this confusion. Thus it was said properly enough in the contemporary accounts, for instance in Lord Monmouth's Memoirs, that Queen Elizabeth died on the last day of the year 1602, for she died on the 24th of March; and by a careful writer this event would have been dated as March 24, $\frac{1602}{1603}$. But many writers, misled by the phrase above cited, have asserted that James I. was proclaimed on the 1st of January 1603. Heber, bishop of Calcutta, again, has ruined the entire chronology of the life of Jeremy Taylor, and unconsciously vitiated the facts, by not understanding this fractional date. Mr Roscoe even too often leaves his readers to collect the true year as they can: thus, *e. g.* at p. 503 of his Life, he quotes from Pope's letter to Warburton, in great vexation for the surreptitious publication of his letters in Ireland, under date of February 4, $174\frac{0}{1}$. But why not have printed it intelligibly as 1741? Incidents there are in most men's lives, which are susceptible of a totally different moral value, according as they are dated in one year or another. That might be a kind and honourable liberality in 1740, which would be a fraud upon creditors in 1741. Exile to a distance of ten miles from London in January 1744, might argue, that a man was a turbulent citizen, and suspected of treason; whilst the same exile in January 1745 would simply argue that, as a Papist, he had been included amongst his whole body in a general measure of precaution to meet the public dangers of that year. This explanation we have thought it right to make, both for its extensive application to *all* editions of Pope, and on account of the serious blunders which have arisen from the case when ill understood; and because, in a work upon education, written jointly by Messrs Lant Carpenter and Shephard, though generally men of ability and learning, this whole point is erroneously explained.

[1] It is apparently with allusion to this part of his history, which he would often have heard from the lips of his own father, that Pope glances at his uncle's memory somewhat disrespectfully in his prose letter to Lord Harvey.

Some accounts, however, say to Flanders, in which case, perhaps, Antwerp or Brussels would have the honour of his conversion.

out serious injury, and was not farther tormented by cows or schoolmasters until he was about eight years old, when the family priest, that is, we presume, the confessor of his parents, taught him, agreeably to the Jesuit system, the rudiments of Greek and Latin concurrently. This priest was named Banister; and his name is frequently employed, together with other fictitious names, by way of signature to the notes in the Dunciad, an artifice which was adopted for the sake of giving a characteristic variety to the notes, according to the tone required for the illustration of the text. From his tuition Pope was at length dismissed to a Catholic school at Twyford, near Winchester. The selection of a school in this neighbourhood, though certainly the choice of a Catholic family was much limited, points apparently to the old Hampshire connection of his father. Here an incident occurred which most powerfully illustrates the original and constitutional determination to satire of this irritable poet. He knew himself so accurately, that in after times, half by way of boast, half of confession, he says,

> But touch me, and no Minister so sore:
> Whoe'er offends, at some unlucky time
> Slides into verse and hitches in a rhyme,
> Sacred to ridicule his whole life long,
> And the sad burthen of some merry song.

Already, it seems, in childhood he had the same irresistible instinct, victorious over the strongest sense of personal danger. He wrote a bitter satire upon the presiding pedagogue, was brutally punished for this youthful indiscretion, and indignantly removed by his parents from the school. Mr Roscoe speaks of Pope's personal experience as necessarily unfavourable to public schools; but in reality he knew nothing of public schools. All the establishments for Papists were narrow, and suited to their political depression; and his parents were too sincerely anxious for their son's religious principles to risk the contagion of Protestant association by sending him elsewhere.

From the scene[1] of his disgrace and illiberal punishment, he passed, according to the received accounts, under the tuition of several other masters in rapid succession. But it is the less necessary to trouble the reader with their names, as Pope himself assures us that he learned nothing from any of them. To Banister he had been indebted for such trivial elements of a schoolboy's learning as he possessed at all, excepting those which he had taught himself. And upon himself it was, and his own admirable faculties, that he was now finally thrown for the rest of his education, at an age so immature that many boys are then first entering their academic career. Pope is supposed to have been scarcely twelve years old when he assumed the office of self-tuition, and bade farewell for ever to schools and tutors.

Such a phenomenon is at any rate striking: it is the more so, under the circumstances which attended the plan, and under the results which justified its execution. It seems, as regards the plan, hardly less strange that prudent parents should have acquiesced in a scheme of so much peril to his intellectual interests, than that the son, as regards the execution, should have justified their confidence by his final success. More especially this confidence surprises us in the father. A doating mother might shut her eyes to all remote evils in the present gratification to her affections; but Pope's father was a man of sense and principle; he must have weighed the risks besetting a boy left to his own intellectual guidance; and to these risks he would allow the more weight from his own conscious defect of scholarship and inability to guide or even to accompany his son's studies. He could neither direct the proper choice of studies; nor in any one study taken separately could he suggest the proper choice of books.

The case we apprehend to have been this: Alexander Pope the elder, was a man of philosophical desires and unambitious character. Quiet and seclusion and innocence of life,—these were what he affected for himself; and that which had been found available for his own happiness, he might reasonably wish for his son. The two hinges upon which his plans may be supposed to have turned, were, first, the political degradation of his sect; and, secondly, the fact that his son was an only child. Had he been a Protestant, or had he, though a Papist, been burthened with a large family of children, he would doubtless have pursued a different course. But to him, and, as he sincerely hoped, to his son, the strife after civil honours was sternly barred. Apostacy only could lay it open. And, as the sentiments of honour and duty in this point fell in with the vices of his temperament, high principle concurring with his constitutional love of ease, we need not wonder that he should early retire from commerce with a very moderate competence, or that he should suppose the same fortune sufficient for one who was to stand in the same position. This son was from his birth deformed. That made it probable that he might not marry. If he should, and happened to have children, a small family would find an adequate provision in the patrimonial funds; and a large one at the worst could only throw him upon the same commercial exertions to which he had been obliged himself. The Roman Catholics, indeed, were just then situated as our modern Quakers are: law to the one, as conscience to the other, closed all modes of active employment except that of commercial industry. Either his son, therefore, would be a rustic recluse, or, like himself, he would be a merchant.

---

[1] This however was not Twyford, according to an anonymous pamphleteer of the times, but a Catholic seminary in Devonshire Street, that is, in the Bloomsbury district of London; and the same author asserts, that the scene of his disgrace, as indeed seems probable beforehand, was not the first, but the last of his arenas as a schoolboy. Which indeed was first and which last, is very unimportant; but with a view to another point, which is not without interest, namely, as to the motive of Pope for so bitter a lampoon as we must suppose it to have been, as well as with regard to the topics which he used to season it, this anonymous letter throws the only light which has been offered; and strange it is, that no biographer of Pope should have hunted upon the traces indicated by him. Any solution of Pope's virulence, and of the master's bitter retaliation, even *as* a solution, is so far entitled to attention; apart from which the mere straightforwardness of this man's story, and its minute circumstantiality, weigh greatly in its favour. To our thinking, he unfolds the whole affair in the simple explanation, nowhere else to be found, that the master of the school, the mean avenger of a childish insult by a bestial punishment, was a Mr Bromley, one of James II.'s Popish apostates; whilst the particular statements which he makes with respect to himself and the young Duke of Norfolk of 1700, as two schoolfellows of Pope at that time and place, together with his voluntary promise to come forward in person, and verify his account if it should happen to be challenged,—are all, we repeat, so many presumptions in favour of his veracity. "Mr Alexander Pope," says he, "before he had been four months at this school, or was able to construe Tully's Offices, employed his muse in satirizing his master. It was a libel of at least one hundred verses, which (a fellow-student having given information of it) was found in his pocket; and the young satirist was soundly whipped, and kept a prisoner to his room for seven days; whereupon his father fetched him away, and I have been told he never went to school more." This Bromley, it has been ascertained, was the son of a country gentleman in Worcestershire, and must have had considerable prospects at one time, since it appears that he had been a gentleman-commoner at Christ's Church, Oxford. There is an error in the punctuation of the letter we have just quoted, which affects the sense in a way very important to the question before us. Bromley is described as "one of King James's converts in Oxford, some years *after* that prince's abdication;" but, if this were really so, he must have been a conscientious convert. The latter clause should be connected with what follows: "*Some years after that prince's abdication he kept a little seminary;*" that is, when his mercenary views in quitting his religion were effectually defeated, when the Boyne had sealed his despair, he humbled himself into a petty schoolmaster. These facts are interesting, because they suggest at once the motive for the merciless punishment inflicted upon Pope. His own father was a Papist like Bromley, but a sincere and honest Papist, who had borne double taxes, legal stigmas, and public hatred for conscience' sake. His contempt was habitually pointed at those who tampered with religion for interested purposes. His son inherited these upright feelings. And we may easily guess what would be the bitter sting of any satire he would write on Bromley. Such a topic was too true to be forgiven, and too keenly barbed by Bromley's conscience. By the way, this writer, like ourselves, reads in this juvenile adventure a prefiguration of Pope's satirical destiny.

With such prospects, what need of an elaborate education? And where was such an education to be sought? At the petty establishments of the suffering Catholics, the instruction, as he had found experimentally, was poor. At the great national establishments his son would be a degraded person; one who was permanently repelled from every arena of honour, and sometimes, as in cases of public danger, was banished from the capital, deprived of his house, left defenceless against common ruffians, and rendered liable to the control of every village magistrate. To one in these circumstances solitude was the wisest position; and the best qualification for that was an education that would furnish aids to solitary thought. No need for brilliant accomplishments to him who must never display them; forensic arts, pulpit erudition, senatorial eloquence, academical accomplishments—these would be lost to one against whom the courts, the pulpit, the senate, the universities, were closed. Nay, by possibility worse than lost; they might prove so many snares or positive bribes to apostacy. Plain English, therefore, and the high thinking of his compatriot authors, might prove the best provision for the mind of an English Papist destined to seclusion.

Such are the considerations under which we read and interpret the conduct of Pope's parents; and they lead us to regard as wise and conscientious a scheme which, under ordinary circumstances, would have been pitiably foolish. And be it remembered, that to these considerations, derived exclusively from the civil circumstances of the family, were superadded others derived from the astonishing prematurity of the individual. That boy who could write at twelve years of age the beautiful and touching stanzas on Solitude, might well be trusted with the superintendence of his own studies. And the stripling of sixteen, who could so far transcend in good sense the accomplished statesmen or men of the world with whom he afterwards corresponded, might challenge confidence for such a choice of books as would best promote the development of his own faculties.

In reality, one so finely endowed as Alexander Pope, could not easily lose his way in the most extensive or ill-digested library. And though he tells Atterbury, that at one time he abused his opportunities by reading controversial divinity, we may be sure that his own native activities, and the elasticity of his mind, would speedily recoil into a just equilibrium of study, under wider and happier opportunities. Reading, indeed, for a person like Pope, is rather valuable as a means of exciting his own energies, and of feeding his own sensibilities, than for any direct acquisitions of knowledge, or for any trains of systematic research. All men are destined to devour much rubbish between the cradle and the grave; and doubtless the man who is wisest in the choice of his books, will have read many a page before he dies that a thoughtful review would pronounce worthless. This is the fate of all men. But the reading of Pope, as a general result or measure of his judicious choice, is best justified in his writings. They show him well furnished with whatsoever he wanted for matter or for embellishment, for argument or illustration, for example and model, or for direct and explicit imitation.

Possibly, as we have already suggested, within the range of English literature Pope might have found all that he wanted. But variety the widest has its uses; and, for the extension of his influence with the polished classes amongst whom he lived, he did wisely to add other languages; and a question has thus arisen with regard to the extent of Pope's attainments as a self-taught linguist. A man, or even a boy, of great originality, may happen to succeed best, in working his own native mines of thought, by his unassisted energies: here it is granted that a tutor, a guide, or even a companion, may be dispensed with, and even beneficially. But in the case of foreign languages, in attaining this machinery of literature, though anomalies even here do arise, and men there are, like Joseph Scaliger, who form their own dictionaries and grammars in the mere process of reading an unknown language, by far the major part of students will lose their time by rejecting the aid of tutors. As there has been much difference of opinion with regard to Pope's skill in languages, we shall briefly collate and bring into one focus the stray notices.

As to the French, Voltaire, who knew Pope personally, declared that he "could hardly *read* it, and spoke not one syllable of the language." But perhaps Voltaire might dislike Pope? On the contrary, he was acquainted with his works, and admired them to the very level of their merits. Speaking of him *after death* to Frederick of Prussia, he prefers him to Horace and Boileau, asserting that, by comparison with *them*,

> Pope *approfondit* ce qu'ils ont *effleuré*.
> D'un esprit plus hardi, d'un pas plus assuré,
> Il porta le flambeau dans l'abîme de l'être;
> Et l'homme *avec lui seul* apprit à se connoître.
> L'art quelquefois frivole, et quelquefois divine,
> L'art des vers est dans Pope utile au genre humain.

This is not a wise account of Pope, for it does not abstract the characteristic feature of his power; but it is a very kind one. And of course Voltaire could not have meant any unkindness in denying his knowledge of French. But he was certainly wrong. Pope, in *his* presence, would decline to speak or to read a language of which the pronunciation was confessedly beyond him. Or, if he did, the impression left would be still worse. In fact, no man ever will pronounce or talk a language which he does not use, for some part of every day, in the real intercourse of life. But that Pope read French of an ordinary cast with fluency enough, is evident from the extensive use which he made of Madame Dacier's labours on the Iliad, and still more of La Valterie's prose translation of the Iliad. Already in the year 1718, and long before his personal knowledge of Voltaire, Pope had shown his accurate acquaintance with some voluminous French authors, in a way which, we suspect, was equally surprising and offensive to his noble correspondent. The Duke of Buckingham[1] had addressed to Pope a letter, containing some account of the controversy about Homer, which had then been recently carried on in France between La Motte and Madame Dacier. This account was delivered with an air of teaching, which was very little in harmony with its excessive shallowness. Pope, who sustained the part of pupil in this interlude, replied in a manner that exhibited a knowledge of the parties concerned in the controversy much superior to that of the duke. In particular, he characterized the excellent notes upon Horace of M. Dacier the husband in very just terms, as distinguished from those of his conceited and half-learned wife; and the whole reply of Pope seems very much as though he had been playing off a mystification on his grace. Undoubtedly the pompous duke felt that he had caught a Tartar. Now M. Dacier's Horace, which, with the text, fills nine volumes, Pope could not have read *except* in French; for they are not even yet translated into English. Besides, Pope read critically the French translations of his own Essay on Man, Essay on Criticism, Rape of the Lock, &c. He spoke of them as a critic; and it was at no time a fault of Pope's to make false pretensions. All readers of Pope's Satires must also recollect numerous proofs that he had read Boileau with so much feeling of his peculiar merit, that he has appropriated and naturalized in English some of his best passages. Voltaire was, therefore, certainly wrong.

---

[1] That is, Sheffield, and, legally speaking, of Buckingham*shire*. For he would not take the title of Buckingham, under a fear that there was lurking somewhere or other a claim to that title amongst the connections of the Villiers family. He was a pompous grandee, who lived in uneasy splendour, and, as a writer, most extravagantly overrated; accordingly, he is now forgotten. Such was his vanity, and his ridiculous mania for allying himself with royalty, that he first of all had the presumption to court the Princess (afterwards Queen) Anne. Being rejected, he then offered himself to the illegitimate daughter of James II., by the daughter of Sir Charles Sedley. She was as ostentatious as himself, and accepted him.

Of Italian literature, meantime, Pope knew little or nothing; and simply because he knew nothing of the language. Tasso, indeed, he admired; and, which is singular, more than Ariosto. But we believe that he had read him only in English; and it is certain that he could not take up an Italian author, either in prose or verse, for the unaffected amusement of his leisure.

Greek, we all know, has been denied to Pope, ever since he translated Homer, and chiefly in consequence of that translation. This seems at first sight unfair, because criticism has not succeeded in fixing upon Pope any errors of ignorance. His deviations from Homer were uniformly the result of imperfect sympathy with the naked simplicity of the antique, and therefore wilful deviations, not (like those of his more pretending competitors, Addison and Tickell) pure blunders of misapprehension. But yet it is not inconsistent with this concession to Pope's merits, that we must avow our belief in his thorough ignorance of Greek when he first commenced his task. And to us it seems astonishing that nobody should have adverted to that fact as a sufficient solution, and in fact the only plausible solution, of Pope's excessive depression of spirits in the earliest stage of his labours. This depression, after he had once pledged himself to his subscribers for the fulfilment of his task, arose from, and could have arisen from nothing else than, his conscious ignorance of Greek in connection with the solemn responsibilities he had assumed in the face of a great nation. Nay, even countries as presumptuously disdainful of tramontane literature as Italy took an interest in this memorable undertaking. Bishop Berkeley found Salvini reading it at Florence; and Madame Dacier even, who read little but Greek, and certainly no English until then, condescended to study it. Pope's dejection, therefore, or rather agitation (for it impressed by sympathy a tumultuous character upon his dreams, which lasted for years after the cause had ceased to operate) was perfectly natural under the explanation we have given, but not otherwise. And how did he surmount this unhappy self-distrust? Paradoxical as it may sound, we will venture to say, that, with the innumerable aids for interpreting Homer which even then existed, a man sufficiently acquainted with Latin might make a translation even critically exact. This Pope was not long in discovering. Other alleviations of his labour concurred, and in a ratio daily increasing.

The same formulæ were continually recurring, such as,

But him answering, thus addressed the swift-footed Achilles;

Or,

But him sternly beholding, thus spoke Agamemnon the king of men.

Then, again, universally the Homeric Greek, from many causes, is easy; and especially from these two: 1*st*, The simplicity of the thought, which never gathers into those perplexed knots of rhetorical condensation which we find in the dramatic poets of a higher civilization: 2*dly*, From the constant bounds set to the expansion of the thought by the form of the metre; an advantage of verse which makes the poets so much easier to a beginner in the German language than the illimitable weavers of prose. The line or the stanza reins up the poet tightly to his theme, and will not suffer him to expatiate. Gradually, therefore, Pope came to read the Homeric Greek, but never accurately; nor did he ever read Eustathius without aid from Latin. As to any knowledge of the Attic Greek, of the Greek of the dramatists, the Greek of Plato, the Greek of Demosthenes, Pope neither had it nor affected to have it. Indeed it was no foible of Pope's, as we will repeat, to make claims which he had not, or even to dwell ostentatiously upon those which he had. And with respect to Greek in particular, there is a manuscript letter in existence from Pope to a Mr Bridges at Falham, which, speaking of the original Homer, distinctly records the knowledge which he had of his own "imperfectness in the language." Chapman, a most spirited translator of Homer, probably had no very critical skill in Greek; and Hobbes was, beyond all question, as poor a Grecian as he was a doggerel translator; yet in this letter Pope professes his willing submission to the "authority" of Chapman and Hobbes, as superior to his own.

Finally, in *Latin* Pope was a "considerable proficient," even by the cautious testimony of Dr Johnson; and in this language only the doctor was an accomplished critic. If Pope had really the proficiency here ascribed to him, he must have had it already in his boyish years; for the translation from Statius, which is the principal monument of his skill, was executed *before* he was fourteen. We have taken the trouble to throw a hasty glance over it; and whilst we readily admit the extraordinary talent which it shows, as do all the juvenile essays of Pope, we cannot allow that it argues any accurate skill in Latin. The word Malĕa, as we have seen noticed by some editor, he makes Malēa; which in itself, as the name was not of common occurrence, would not have been an error worth noticing; but, taken in connection with the certainty that Pope had the original line before him—

Arripit ex templo Maleæ de valle resurgens,

when not merely the scanning theoretically, but the whole rhythmus practically, to the most obtuse ear, would be annihilated by Pope's false quantity, is a blunder which serves to show his utter ignorance of prosody. But, even as a version of the sense, with every allowance for a poet's license of compression and expansion, Pope's translation is defective, and argues an occasional inability to construe the text. For instance, at the council summoned by Jupiter, it is said that he at his first entrance seats himself upon his starry throne, but not so the inferior gods;

Nec protinus ausi
Cœlicolæ, veniam donec pater ipse sedendi
Tranquilla jubet esse manu.

In which passage there is a slight obscurity, from the ellipsis of the word *sedere*, or *sese locare;* but the meaning is evidently that the other gods did not presume to sit down *protinus*, that is, in immediate succession to Jupiter, and interpreting his example as a tacit license to do so, until, by a gentle wave of his hand, the supreme father signifies his express permission to take their seats. But Pope, manifestly unable to extract any sense from the passage, translates thus:

At Jove's assent the deities around
In solemn state the consistory *crown'd;*

where at once the whole picturesque solemnity of the celestial ritual melts into the vaguest generalities. Again, at

v. 178, *ruptæque vices* is translated "*and all the ties of nature broke*;" but by *vices* is indicated the alternate reign of the two brothers, as ratified by mutual oaths, and subsequently violated by Eteocles. Other mistakes might be cited, which seem to prove that Pope, like most self-taught linguists, was a very imperfect one.[1] Pope, in short, never rose to such a point in classical literature as to read either Greek or Latin authors without effort, and for his private amusement.

The result, therefore, of Pope's self-tuition appears to us, considered in the light of an attempt to acquire certain accomplishments of knowledge, a most complete failure. As a linguist, he read no language with ease; none with pleasure to himself; and none with so much accuracy as could have carried him through the most popular author with a general independence on interpreters. But, considered with a view to his particular faculties and slumbering originality of power, which required perhaps the stimulation of accident to arouse them effectually, we are very much disposed to think that the very failure of his education as an artificial training was a great advantage finally for inclining his mind to throw itself, by way of indemnification, upon its native powers. Had he attained, as with better tuition he would have attained, distinguished excellence as a scholar, or as a student of science, the chances are many that he would have settled down into such studies as thousands could pursue not less successfully than he; whilst as it was, the very dissatisfaction which he could not but feel with his slender attainments must have given him a strong motive for cultivating those impulses of original power which he felt continually stirring within him, and which were vivified into trials of competition as often as any distinguished excellence was introduced to his knowledge.

Pope's father, at the time of his birth, lived in Lombard Street;[2] a street still familiar to the public eye, from its adjacency to some of the chief metropolitan establishments, and to the English ear possessing a degree of historical importance; first, as the residence of those Lombards, or Milanese, who affiliated our infant commerce to the matron splendours of the Adriatic and the Mediterranean; next, as the central resort of those jewellers, or "goldsmiths," as they were styled, who performed all the functions of modern bankers from the period of the parliamentary war to the rise of the Bank of England, that is, for six years after the birth of Pope; and, lastly, as the seat, until lately, of that vast Post Office, through which, for so long a period, has passed the correspondence of all nations and languages, upon a scale unknown to any other country. In this street Alexander Pope the elder had a house, and a warehouse, we presume, annexed, in which he conducted the wholesale business of a linen merchant. As soon as he had made a moderate fortune he retired from business, first to Kensington, and afterwards to Binfield, in Windsor Forest. The period of this migration is not assigned by any writer. It is probable that a prudent man would not adopt it with any prospect of having more children. But this chance might be considered as already extinguished at the birth of Pope; for though his father had then only attained his forty-fourth year, Mrs Pope had completed her forty-eighth. It is probable, from the interval of seven days which is said to have elapsed between Pope's punishment and his removal from the school, that his parents were then living at such a distance from him as to prevent his ready communication with them, else we may be sure that Mrs Pope would have flown on the wings of love and wrath to the rescue of her darling. Supposing, therefore, as we *do* suppose, that Mr Bromley's school in London was the scene of his disgrace, it would appear on this argument that his parents were then living in Windsor Forest. And this hypothesis falls in with another anecdote in Pope's life, which we know partly upon his own authority. He tells Wycherley that he had seen Dryden, and barely seen him. *Virgilium vidi tantum.* This is presumed to have been in Will's Coffee-house, whither any person in search of Dryden would of course resort; and it must have been before Pope was twelve years old, for Dryden died in 1700. Now there is a letter of Sir Charles Wogan's, stating that he first took Pope to Will's; and his words are, "from our forest." Consequently, at that period, when he had not completed his twelfth year, Pope was already living in the forest.

From this period, and so long as the genial spirits of youth lasted, Pope's life must have been one dream of pleasure. He tells Lord Harvey that his mother did not spoil him; but that was no doubt because there was no room for wilfulness or waywardness on either side, when all was one placid scene of parental obedience and gentle filial authority. We feel persuaded that, if not in words, in spirit and inclination, they would, in any notes they might have occasion to write, subscribe themselves "your dutiful parents." And of what consequence in whose hands were the reins which were never needed? Every reader must be pleased to know that these idolizing parents lived to see their son at the very summit of his public elevation; even his father lived two years and a half after the publication of his Homer had commenced, and when his fortune was made; and his mother lived for nearly eighteen years more. What a felicity for her, how rare and how perfect, to find that he, who to her maternal eyes was naturally the most perfect of human beings, and the idol of her heart, had already been the idol of the nation before he had completed his youth. She had also another blessing not always commanded by the most devoted love; many sons there are who think it essential to manliness that they should treat their mother's doating anxiety with levity, or even ridicule. But Pope, who was the model of a good son, never swerved in words, manners, or conduct, from the most respectful tenderness, or intermitted the piety of his attentions. And so far did he carry this regard for his mother's comfort, that, well knowing how she lived upon his presence or by his image, he denied himself for many years all excursions which could not be fully accomplished within the revolution of a week. And to this cause, combined with the excessive length of his mother's life, must be ascribed the fact that Pope never went abroad; not to Italy with Thomson or with Berkeley, or any of his diplomatic friends; not to Ireland, where his presence would have been hailed as a national honour; not even to France, on a visit to his admiring and admired friend Lord Bolingbroke. For as to the fear of sea-sickness, *that* did not arise until a late period of his life; and at any period would not have operated to prevent his crossing from Dover to Calais. It is possible that, in his earlier and more sanguine years, all the perfection of his filial love may not have availed to prevent him from now and then breathing a secret murmur at confinement so constant. But it is certain that, long before he passed the meridian of his life, Pope had come to view this confinement with far other thoughts. Experience had then taught him, that to no man is the privilege granted of possessing more than one or two friends who are such in extremity. By that time he had come to view his mother's death with fear and anguish. She, he knew by many a sign, would have been happy to lay down her life for his sake; but for others, even those who were the most friendly and the most constant in their attentions, he felt but too certainly that his death, or his heavy affliction, might cost them a few sighs, but would not materially disturb their peace of mind. "It is but in a very narrow circle," says he, in a confidential letter, "that friendship walks in this world, and I care not to tread out of it more than I needs must; knowing well it is but to two or three (if quite so many) that any man's welfare or memory can be of consequence." After such acknowledgements, we are not surprised to find him writing thus of his mother, and his fearful struggles to fight off the shock of his mother's death, at a time when it was rapidly approaching. After having said of a friend's death, "the subject is beyond writing upon, beyond cure or ease by reason or reflection, beyond all but one thought, that it is the will of God," he goes on thus, "So will the death of my mother be, which now I tremble at, now resign to, now bring close to me, now set farther off; every day alters, turns me about, confuses my whole frame of mind." There is no pleasure, he adds, which the world can give "equivalent to countervail either the death of one I have so long lived with, or of one I have so long lived for." How will he comfort himself after her death? "I have nothing left but to turn my thoughts to one comfort, the last we usually think of, though the only one we should in wisdom depend upon. I sit in her room, and she is always present before me but when I sleep. I wonder I am so well. I have shed many tears; but now I weep at nothing."

---

[1] Meantime, the felicities of this translation are at times perfectly astonishing; and it would be scarcely possible to express more nervously or amply the words,

——————*jurisque secundi*
Ambitus impatiens, et summo dulcius unum
Stare loco——————

than this child of fourteen has done in the following couplet, which, most judiciously, by reversing the two clauses, gains the power of fusing them into connection:

And impotent desire to reign alone,
That scorns the dull reversion of a throne.

But the passage for which beyond all others we must make room, is a series of eight lines, corresponding to six in the original; and this for two reasons: First, Because Dr Joseph Warton has deliberately asserted, that in our whole literature, "we have scarcely eight more beautiful lines than these;" and though few readers will subscribe to so sweeping a judgment, yet certainly these must be wonderful lines for a boy, which could challenge such commendation from an experienced *polyhistor* of infinite reading. Secondly, Because the lines contain a night-scene. Now it must be well known to many readers, that the famous night-scene in the Iliad, so familiar to every school-boy, has been made the subject, for the last thirty years, of severe, and, in many respects, of just criticisms. This description will therefore have a double interest by comparison; whilst, whatever may be thought of either taken separately for itself, considered as a translation, this which we now quote is as true to Statius as the other is undoubtedly faithless to Homer:

Jamque per emeriti surgens confinia Phœbi
Titanis, late mundo subvecta silenti
Rorifera gelidum tenuaverat aera biga.
Jam pecudes volucresque tacent: jam somnus avaris
Inserpit curis, pronusque per aera nutat,
Grata laboratæ referens oblivia vitæ.
Theb. i. 336–341.

'Twas now the time when Phœbus yields to night,
And rising Cynthia sheds her silver light;
Wide o'er the world in solemn pomp she drew
Her airy chariot hung with pearly dew.
All birds and beasts lie hush'd. Sleep steals away
The wild desires of men and toils of day;
And brings, descending through the silent air,
A sweet forgetfulness of human care.

[2] One writer of that age says, in Cheapside; but probably this difference arose from contemplating Lombard Street as a prolongation of Cheapside.

A man, therefore, happier than Pope in his domestic relations cannot easily have lived. It is true these relations were circumscribed; had they been wider they could not have been so happy. But Pope was equally fortunate in his social relations. What, indeed, most of all surprises us, is the courteous, flattering, and even brilliant reception which Pope found from his earliest boyhood amongst the most accomplished men of the world. Wits, courtiers, statesmen, grandees the most dignified, and men of fashion the most brilliant, all alike treated him not only with pointed kindness, but with a respect that seemed to acknowledge him as their intellectual superior. Without rank, high birth, fortune, without even a literary name, and in defiance of a deformed person, Pope, whilst yet only sixteen years of age, was caressed, and even honoured; and all this with no one recommendation but simply the knowledge of his dedication to letters, and the premature expectations which he raised of future excellence. Sir William Trumbull, a veteran statesman, who had held the highest stations, both diplomatic and ministerial, made him his daily companion. Wycherley, the old *roué* of the town, a second-rate wit, but not the less jealous on that account, showed the utmost deference to one whom, as a man of fashion, he must have regarded with contempt, and between whom and himself there were nearly "fifty good years of fair and foul weather." Cromwell,[1] a fox-hunting country gentleman, but uniting with that character the pretensions of a wit, and affecting also the reputation of a rake, cultivated his regard with zeal and conscious inferiority. Nay, which never in any other instance happened to the most fortunate poet, his very inaugural essays in verse were treated, not as prelusive efforts of auspicious promise, but as finished works of art, entitled to take their station amongst the literature of the land; and in the most worthless of all his poems, Walsh, an established authority, and whom Dryden pronounced the ablest critic of the age, found proofs of equality with Virgil.

The literary correspondence with these gentlemen is interesting, as a model of what once passed for fine letter-writing. Every nerve was strained to outdo each other in carving all thoughts into a fillagree work of rhetoric; and the amœbæan contest was like that between two village-cocks from neighbouring farms endeavouring to overcrow each other. To us, in this age of purer and more masculine taste, the whole scene takes the ludicrous air of old and young fops dancing a minuet with each other, practising the most elaborate grimaces, sinkings and risings the most awful, bows the most overshadowing, until plain walking, running, or the motions of natural dancing, are thought too insipid for endurance. In this instance the taste had perhaps really been borrowed from France, though often enough we impute to France what is the native growth of all minds placed in similar circumstances. Madame de Sevigné's Letters were really models of grace. But Balzac, whose letters, however, are not without interest, had in some measure formed himself upon the truly magnificent rhetoric of Pliny and Seneca. Pope and his correspondents, meantime, degraded the dignity of rhetoric, by applying it to trivial commonplaces of compliment; whereas Seneca applied it to the grandest themes which life or contemplation can supply. Lady Mary Wortley Montagu, on first coming amongst the wits of the day, naturally adopted their style. She found this sort of *euphuism* established; and it was not for a very young woman to oppose it. But her masculine understanding and powerful good sense, shaken free, besides, from all local follies by travels and extensive commerce with the world, first threw off these glittering chains of affectation. Dean Swift, by the very constitution of his mind, plain, sinewy, nervous, and courting only the strength that allies itself with homeliness, was always indisposed to this mode of correspondence. And, finally, Pope himself, as his earlier friends died off, and his own understanding acquired strength, laid it aside altogether. One reason doubtless was, that he found it too fatiguing; since in this way of letter-writing he was put to as much expense of wit in amusing an individual correspondent as would for an equal extent have sufficed to delight the whole world. A funambulist may harass his muscles and risk his neck on the tight-rope, but hardly to entertain his own family. Pope, however, had another reason for declining this showy system of fencing; and strange it is that he had not discovered this reason from the very first. As life advanced, it happened unavoidably that real business advanced; the careless condition of youth prompted no topics, or at least prescribed none, but such as were agreeable to the taste, and allowed of an ornamental colouring. But when downright business occurred, exchequer bills to be sold, meetings to be arranged, negotiations confided, difficulties to be explained, here and there by possibility a jest or two might be scattered, a witty allusion thrown in, or a sentiment interwoven; but for the main body of the case, it neither could receive any ornamental treatment, nor if, by any effort of ingenuity, it *had*, could it look otherwise than silly and unreasonable:

---

[1] Dr Johnson said, that all he could discover about Mr Cromwell, was the fact of his going a hunting in a tie-wig; but Gay has added another fact to Dr Johnson's, by calling him "honest *hatless* Cromwell with red breeches." This epithet has puzzled the commentators; but its import is obvious enough. Cromwell, as we learn from more than one person, was anxious to be considered a fine gentleman, and devoted to women. Now it was long the custom in that age for such persons, when walking with ladies, to carry their hats in their hand. Louis XV. used to ride by the side of Madame de Pompadour hat in hand.

> Ornari res ipsa negat, contenta doceri.

Pope's idleness, therefore, on the one hand, concurring with good sense and the necessities of business on the other, drove him to quit his gay rhetoric in letter-writing. But there are passages surviving in his correspondence which indicate, that, after all, had leisure and the coarse perplexities of life permitted it, he still looked with partiality upon his youthful style, and cherished it as a first love. But in this harsh world, as the course of true love, so that of rhetoric, never did run smooth; and thus it happened that, with a lingering farewell, he felt himself forced to bid it adieu. Strange that any man should think his own sincere and confidential overflowings of thought and feeling upon books, men, and public affairs, less valuable in a literary view than the legerdemain of throwing up bubbles into the air for the sake of watching their prismatic hues, like an Indian juggler with his cups and balls. We of this age, who have formed our notions of epistolary excellence from the chastity of Gray's, the brilliancy of Lady Mary Wortley Montagu's during her later life, and the mingled good sense and fine feeling of Cowper's, value only those letters of Pope which he himself thought of inferior value. And even with regard to these, we may say that there is a great mistake made; the best of those later letters between Pope and Swift, &c. are not in themselves at all superior to the letters of sensible and accomplished women, such as leave every town in the island by every post. Their chief interest is a derivative one; we are pleased with any letter, good or bad, which relates to men of such eminent talent; and sometimes the subjects discussed have a separate interest for themselves. But as to the quality of the discussion, apart from the person discussing and the thing discussed, so trivial is the value of these letters in a large proportion, that we cannot but wonder at the preposterous value which was set upon them by the writers.[1] Pope especially ought not to have his ethereal works loaded by the mass of trivial prose which is usually attached to them.

This correspondence, meantime, with the wits of the time, though one mode by which, in the absence of reviews, the reputation of an author was spread, did not perhaps serve the interests of Pope so effectually as the poems which in this way he circulated in those classes of English society whose favour he chiefly courted. One of his friends, the truly kind and accomplished Sir William Trumbull, served him in that way, and perhaps in another eventually even more important. The library of Pope's father was composed exclusively of polemical divinity, a proof, by the way, that he was not a blind convert to the Roman Catholic faith; or, if he was so originally, had reviewed the grounds of it, and adhered to it after strenuous study. In this dearth of books at his own home, and until he was able to influence his father in buying more extensively, Pope had benefited by the loans of his friends; amongst whom it is probable that Sir William, as one of the best scholars of the whole, might assist him most. He certainly offered him the most touching compliment, as it was also the wisest and most paternal counsel, when he besought him, as one *goddess-born*, to quit the convivial society of deep-drinkers:

> Heu, fuge nate dea, teque his, ait, eripe malis.

With these aids from friends of rank, and his way thus laid open to public favour, in the year 1709 Pope first came forward upon the stage of literature. The same year which terminated his legal minority introduced him to the public. *Miscellanies* in those days were almost periodical repositories of fugitive verse. Tonson happened at this time to be publishing one of some extent, the sixth volume of which offered a sort of ambush to the young aspirant of Windsor Forest, from which he might watch the public feeling. The volume was opened by Mr Ambrose Philips, in the character of pastoral poet; and in the same character, but stationed at the end of the volume, and thus covered by his bucolic leader, as a soldier to the rear by the file in advance, appeared Pope; so that he might win a little public notice, without too much seeming to challenge it. This half-clandestine emersion upon the stage of authorship, and his furtive position, are both mentioned by Pope as accidents, but as accidents in which he rejoiced, and not improbably accidents which Tonson had arranged with a view to his satisfaction.

It must appear strange that Pope at twenty-one should choose to come forward for the first time with a work composed at sixteen. A difference of five years at that stage of life is of more effect than of twenty at a later; and his own expanding judgment could hardly fail to inform him that his Pastorals were by far the worst of his works. In reality, let us not deny, that had Pope never written any thing else, his name would not have been known as a name even of promise, but would probably have been redeemed from oblivion by some satirist or writer of a Dunciad. Were a man to meet with such a nondescript monster as the following, viz. "*Love out of Mount Ætna by Whirlwind,*" he would suppose himself reading the Racing Calendar. Yet this hybrid creature is one of the many zoological monsters to whom the Pastorals introduce us:

> I know thee, love! on foreign mountains born,
> Wolves gave thee suck, and savage tigers fed.
> Thou wert from Ætna's burning entrails torn,
> Got by fierce whirlwinds, and in thunder born.

---

[1] It is strange indeed to find, not only that Pope had so frequently kept rough copies of his own letters, and that he thought so well of them as to repeat the same letter to different persons, as in the case of the two lovers killed by lightning, or even to two sisters, Martha and Therese Blount (who were sure to communicate their letters), but that even Swift had retained copies of *his*.

But the very names "Damon" and "Strephon," "Phillis" and "Delia," are rank with childishness. Arcadian life is, at the best, a feeble conception, and rests upon the false principle of crowding together all the luscious sweets of rural life, undignified by the danger which attends pastoral life in our climate, and unrelieved by shades, either moral or physical. And the Arcadia of Pope's age was the spurious Arcadia of the opera theatre, and, what is worse, of the French opera.

The hostilities which followed between these rival wooers of the pastoral muse are well known. Pope, irritated at what he conceived the partiality shown to Philips in the Guardian, pursued the review ironically; and, whilst affecting to load his antagonist with praises, draws into pointed relief some of his most flagrant faults. The result, however, we cannot believe. That all the wits, except Addison, were duped by the irony, is quite impossible. Could any man of sense mistake for praise the remark, that Philips had imitated "*every* line of Strada;" that he had introduced wolves into England, and proved himself the first of gardeners by making his flowers "blow all in the same season." Or, suppose those passages unnoticed, could the broad sneer escape him, where Pope taxes the other writer (viz. himself) with having deviated "into downright poetry;" or the outrageous ridicule of Philip's style, as setting up for the ideal type of the pastoral style, the quotation from Gay, beginning,

> Rager, go vetch tha kee, or else tha zun
> Will quite bego before ch' 'avs half a don!

Philips is said to have resented this treatment by threats of personal chastisement to Pope, and even hanging up a rod at Button's coffee-house. We may be certain that Philips never disgraced himself by such ignoble conduct. If the public indeed were universally duped by the paper, what motive had Philips for resentment? Or, in any case, what plea had he for attacking Pope, who had not come forward as the author of the essay? But, from Pope's confidential account of the matter, we know that Philips saw him daily, and never offered him "any indecorum;" though, for some cause or other, Pope pursued Philips with virulence through life.

In the year 1711, Pope published his Essay on Criticism, which some people have very unreasonably fancied his best performance; and in the same year his Rape of the Lock, the most exquisite monument of playful fancy that universal literature offers. It wanted, however, as yet, the principle of its vitality, in wanting the machinery of Sylphs and Gnomes, with which addition it was first published in 1714.

In the year 1712, Pope appeared again before the public as the author of the Temple of Fame, and the Elegy to the Memory of an Unfortunate Lady. Much speculation has arisen on the question concerning the name of this lady, and the more interesting question concerning the nature of the persecutions and misfortunes which she suffered. Pope appears purposely to decline answering the questions of his friends upon that point; at least the questions have reached us, and the answers have not. Joseph Warton supposed himself to have ascertained four facts about her: that her name was Wainsbury; that she was deformed in person; that she retired into a convent from some circumstances connected with an attachment to a young man of inferior rank; and that she killed herself, not by a sword, as the poet insinuates, but by a halter. As to the latter statement, it may very possibly be true; such a change would be a very slight exercise of the poet's privileges. As to the rest, there are scarcely grounds enough for an opinion. Pope certainly speaks of her under the name of Mrs (*i. e.* Miss) W——, which at least argues a poetical exaggeration in describing her as a being "that once had *titles*, honour, wealth, and fame;" and he may as much have exaggerated her pretensions to beauty. It is indeed noticeable, that he speaks simply of her *decent* limbs, which, in any English use of the word, does not imply much enthusiasm of praise. She appears to have been the niece of a Lady A——; and Mr Craggs, afterwards secretary of state, wrote to Lady A—— on her behalf, and otherwise took an interest in her fate. As to her being a relative of the Duke of Buckingham's, that rests upon a mere conjectural interpretation applied to a letter of that nobleman's. But all things about this unhappy lady are as yet enveloped in mystery. And not the least part of the mystery is a letter of Pope's to a Mr C——, bearing date 1732, that is, just twenty years after the publication of the poem, in which Pope, in a manly tone, justifies himself for his estrangement, and presses against his unknown correspondent the very blame which he had applied generally to the kinsman of the poor victim in 1712. Now, unless there is some mistake in the date, how are we to explain this gentleman's long lethargy, and his sudden sensibility to Pope's anathema, with which the world had resounded for twenty years?

Pope had now established his reputation with the public as the legitimate successor and heir to the poetical supremacy of Dryden. His Rape of the Lock was unrivalled in ancient or modern literature, and the time had now arrived when, instead of seeking to extend his fame, he might count upon a pretty general support in applying what he had already established to the promotion of his own interest. Accordingly, in the autumn of 1713, he formed a final resolution of undertaking a new translation of the Iliad. It must be observed, that already in 1709, concurrently with his Pastorals, he had published specimens of such a translation; and these had been communicated to his friends some time before. In particular, Sir William Trumbull, on the 9th of April 1708, urged upon Pope a complete translation of both Iliad and Odyssey. Defective skill in the Greek language, exaggeration of the difficulties, and the timidity of a writer as yet unknown, and not quite twenty years old, restrained Pope for five years and more. What he had practised as a sort of *bravura*, for a single effort of display, he recoiled from as a daily task to be pursued through much toil, and a considerable section of his life. However, he dallied with the purpose, starting difficulties in the temper of one who wishes to hear them undervalued; until at length Sir Richard Steele determined him to the undertaking, a fact overlooked by the biographers, but which is ascertained by Ayre's account of that interview between Pope and Addison, probably in 1716, which sealed the rupture between them. In the autumn of 1713, he made his design known amongst his friends. Accordingly, on the 21st of October, we have Lord Lansdown's letter, expressing his great pleasure at the communication; on the 26th, we have Addison's letter encouraging him to the task; and in November of the same year occurs the amusing scene so graphically described by Bishop Kennet, when Dean Swift presided in the conversation, and, amongst other indications of his conscious authority, "instructed a young nobleman, that the best poet in England was Mr Pope, who had *begun* a translation of Homer into English verse, for which he must have them all subscribe: for," says he, "*the author shall not begin to print until I have a thousand guineas for him.*"

If this were the extent of what Swift anticipated from the work, he fell miserably below the result. But, perhaps, he spoke only of a cautionary *arrha* or earnest. As this was unquestionably the greatest literary labour, as to profit, ever executed, not excepting the most lucrative of Sir Walter Scott's, if due allowance be made for the altered value of money, and if we consider the Odyssey as forming part of the labour, it may be right to state the particulars of Pope's contract with Lintot.

The number of subscribers to the Iliad was 575, and the number of copies subscribed for was 654. The work was to be printed in six quarto volumes; and the subscription was a guinea a volume. Consequently by the subscription Pope obtained six times 654 guineas, or L.4218. 6s. (for the guinea then passed for 21s. 6d.); and for the copyright of each volume Lintot offered L.200, consequently L.1200 for the whole six; so that from the Iliad the profit exactly amounted to L.5310. 16s. Of the Odyssey, 574 copies were subscribed for. It was to be printed in five quarto volumes, and the subscription was a guinea a volume. Consequently by the subscription Pope obtained five times 574 guineas, or L.3085. 5s.; and for the copyright Lintot offered L.600. The total sum received therefore by Pope, on account of the Odyssey, was L.3685. 5s. But in this instance he had two coadjutors, Broome and Fenton; between them they translated twelve books, leaving twelve to Pope. The notes also were compiled by Broome; but the Postscript to the notes was written by Pope. Fenton received L.300, Broome L.500. Such at least is Warton's account, and more probable than that of Ruffhead, who not only varies the proportions, but increases the whole sum given to the assistants by L.100. Thus far we had followed the guidance of mere probabilities, as they lie upon the face of the transaction. But we have since detected a written statement of Pope's, unaccountably overlooked by the biographers, and serving of itself to show how negligently they have read the works of their illustrious subject. The statement is entitled to the fullest attention and confidence, not being a hasty or casual notice of the transaction, but pointedly shaped to meet a calumnious rumour against Pope in his character of paymaster; as if he who had found so much liberality from publishers in his own person, were niggardly or unjust as soon as he assumed those relations to others. Broome, it was alleged, had expressed himself dissatisfied with Pope's remuneration. Perhaps he had. For he would be likely to frame his estimate for his own services from the scale of Pope's reputed gains; and those gains would, at any rate, be enormously exaggerated, as uniformly happens where there is a basis of the marvellous to begin with. And, secondly, it would be natural enough to assume the previous result from the Iliad as a fair standard for computation; but in this, as we know, all parties found themselves disappointed, and Broome had the less right to murmur at this, since the arrangement with himself as chief journeyman in the job was one main cause of the disappointment. There was also another reason why Broome should be less satisfied than Fenton. Verse for verse, any one thousand lines of a translation so purely mechanical might stand against any other thousand; and so far the equation of claims was easy. A book-keeper, with a pen behind his ear, and Cocker's Golden Rule open before him, could do full justice to Mr Broome *as a poet* every Saturday night. But Broome had a separate account-current for pure prose against Pope. One he had in conjunction with Fenton for verses delivered on the premises at so much per hundred, on which there could be no demur, except as to the allowance for tare and tret as a discount in favour of Pope. But the prose account, the account for notes, requiring very various degrees of reading and research, allowed of no such easy equation. *There* it was, we conceive, that Broome's discontent arose. Pope, however, declares, that he had given him L.500, thus confirming the proportions of Warton against Ruffhead (that is, in effect, Warburton), and some other advantages which were not in money, nor deductions at all from his own money profits, but which may have been worth so much money to Broome as to give some colourable truth to Ruffhead's allegation of an additional L.100. In direct money, it remains certain that Fenton had three and Broome five hundred pounds. It follows, therefore, that for the Iliad and Odyssey jointly he received a sum of L.8996. 1s., and paid for assistance L.800, which leaves to himself a clear sum of L.8196. 1s. And, in fact, his profits ought to be calculated without deduction, since it was his own choice, from indolence, to purchase assistance.

The Iliad was commenced about October 1713. In the summer of the following year he was so far advanced as to begin making arrangements with Lintot for the printing; and the first two books, in manuscript, were put into the hands of Lord Halifax. In June 1715, between the 10th and 28th, the subscribers received their copies of the first volume; and in July Lintot began to publish that volume generally. Some readers will inquire, who paid for the printing and paper, &c.? All this expense fell upon Lintot, for whom Pope was superfluously anxious. The sagacious bookseller understood what he was about; and, when a pirated edition was published in Holland, he counteracted the injury by printing a cheap edition, of which 7500 copies were sold in a few weeks; an extraordinary proof of the extended interest in literature. The second, third, and fourth volumes of the Iliad, each containing, like the first, four books, were published successively in 1716, 1717, 1718; and in 1720 Pope completed the work by publishing the fifth volume, containing five books, and the sixth, containing the last three, with the requisite supplementary apparatus.

The Odyssey was commenced in 1723 (not 1722, as Mr Roscoe virtually asserts at p. 259), and the publication of it was finished in 1725. The sale, however, was much inferior to that of the Iliad; for which more reasons than one might be assigned. But there can be no doubt that Pope himself depreciated the work, by his undignified arrangements for working by subordinate hands. Such a process may answer in sculpture, because there a quantity of rough-hewing occurs, which can no more be improved by committing it to a Phidias, than a common shop-bill could be improved in its arithmetic by Sir Isaac Newton. But in literature such arrangements are degrading; and, above all, in a work which was but too much exposed already to the presumption of being a mere effort of mechanic skill, or (as Curll said to the House of Lords) "*a knack;*" it was deliberately helping forward that idea to let off parts of the labour. Only think of Milton letting off by contract to the lowest offer, and to be delivered by such a day (for which good security to be found), six books of Paradise Lost. It is true, the great dramatic authors were often *collaborateurs*, but their case was essentially different. The loss, however, fell not upon Pope, but upon Lintot, who, on this occasion, was out of temper, and talked rather broadly of prosecution. But that was out of the question. Pope had acted indiscreetly, but nothing could be alleged against his honour; for he had expressly warned the public, that he did not, as in the other case, profess *to translate*, but to *undertake*[1] *a translation* of the Odyssey. Lintot, however, was no loser absolutely, though he might be so in relation to his expectations; on the contrary, he grew rich, bought land, and became sheriff of the county in which his estates lay.

We have pursued the Homeric labours uninterruptedly from their commencement in 1713 till their final termination in 1725, a period of twelve years or nearly; because this was the task to which Pope owed the dignity, if not the comforts, of his life, since it was this which enabled him to decline a pension from all administrations, and even from his friend Craggs, the secretary, to decline the express offer of L.300 per annum. Indeed Pope is always proud to own his obligations to Homer. In the interval, however, between the Iliad and the Odyssey, Pope listened to proposals made by Jacob Tonson, that he should revise an edition of Shakspeare. For this, which was in fact the first attempt at establishing the text of the mighty poet, Pope obtained but little money, and still less reputation. He received, according to tradition, only L.217. 12s. for his trouble of collation, which must have been considerable, and some other trifling editorial labour. And the opinion of all judges, from the first so unfavourable as to have depreciated the money-value of the book enormously, perhaps from a prepossession of the public mind against the fitness of Pope for executing the dull labours of revision, has ever since pronounced this work the very worst edition in existence. For the edition we have little to plead; but for the editor it is but just to make three apologies. In the *first* place, he wrote a brilliant preface, which, although (like other works of the same class) too much occupied in displaying his own ability, and too often, for the sake of an effective antithesis, doing deep injustice to Shakspeare, yet undoubtedly, as a whole, extended his fame, by giving the sanction and countersign of a great wit to the national admiration. *Secondly*, as Dr Johnson admits, Pope's failure pointed out the right road to his successors. *Thirdly*, even in this failure it is but fair to say, that in a graduated scale of merit, as distributed amongst the long succession of editors through that century, Pope holds a rank proportionable to his age. For the year 1720, he is no otherwise below Theobald, Hanmer, Capell, Warburton, or even Johnson, than as they are successively below each other, and all of them as to accuracy below Steevens, as he again was below Malone and Read.

---

[1] The word *undertake* had not yet lost the meaning of Shakspeare's age, in which it was understood to describe those cases where, the labour being of a miscellaneous kind, some person in chief offered to overlook and conduct the whole, whether with or without personal labour. The modern *undertaker*, limited to the care of funerals, was then but one of numerous cases to which the term was applied.

The gains from Shakspeare would hardly counterbalance the loss which Pope sustained this year from the South Sea bubble. One thing, by the way, is still unaccountably neglected by writers on this question: how it was that the great Mississippi bubble, during the Orleans regency in Paris, should have happened to coincide with that of London. If this were accident, how marvellous that the same insanity should possess the two great capitals of Christendom in the same year? If, again, it were not accident, but due to some common cause, why is not that cause explained? Pope to his nearest friends never stated the amount of his loss. The biographers report that at one time his stock was worth from twenty to thirty thousand pounds. But that is quite impossible. It is true, that as the stock rose at one time a thousand per cent., this would not imply on Pope's part an original purchase beyond twenty-five hundred pounds or thereabouts. But Pope has furnished an argument against *that*, which we shall improve. He quotes, more than once, as applicable to his own case, the old proverbial riddle of Hesiod, ϖλεον ἡμισυ ϖαντος, *the half is more than the whole*. What did he mean by that? We understand it thus: that between the selling and buying, the variations had been such as to sink his shares to one half of the price they had once reached, but, even at that depreciation, to leave him richer on selling out than he had been at first. But the half of L.25,000 would be a far larger sum than Pope could have ventured to risk upon a fund confessedly liable to daily fluctuation. L.3000 would be the utmost he could risk; in which case the half of L.25,000 would have left him so very much richer, that he would have proclaimed his good fortune as an evidence of his skill and prudence. Yet, on the contrary, he wished his friends to understand at times that he had lost. But his friends forgot to ask one important question: was the word *loss* to be understood in relation to the imaginary and nominal wealth which he once possessed, or in relation to the absolute sum invested in the South Sea fund? The truth is, Pope practised on this, as on other occasions, a little finessing, which is the chief foible in his character. His object was, that, according to circumstances, he might vindicate his own freedom from the common mania, in case his enemies should take that handle for attacking him; or might have it in his power to plead poverty, and to account for it, in case he should ever accept that pension which had been so often tendered but never sternly rejected.

In 1723 Pope lost one of his dearest friends, Bishop Atterbury, by banishment; a sentence most justly incurred, and mercifully mitigated by the hostile Whig government. On the bishop's trial a circumstance occurred to Pope which flagrantly corroborated his own belief in his natural disqualification for public life. He was summoned as an evidence on his friend's behalf. He had but a dozen words to say, simply explaining the general tenor of his lordship's behaviour at Bromley, and yet, under this trivial task, though supported by the enthusiasm of his friendship, he broke down. Lord Bolingbroke, returning from exile, met the bishop at the sea-side; upon which it was wittily remarked that they were "exchanged." Lord Bolingbroke supplied to Pope the place, or perhaps more than supplied the place, of the friend he had lost; for Bolingbroke was a free-thinker, and so far more entertaining to Pope, even whilst partially dissenting, than Atterbury, whose clerical profession laid him under restraints of decorum, and latterly, there is reason to think, of conscience.

In 1725, on closing the Odyssey, Pope announces his intention to Swift of quitting the labours of a translator, and thenceforwards applying himself to original composition. This resolution led to the Essay on Man, which appeared soon afterwards; and, with the exception of two labours, which occupied Pope in the interval between 1726 and 1729, the rest of his life may properly be described as dedicated to the further extension of that Essay. The two works which he interposed were a collection of the fugitive papers, whether prose or verse, which he and Dean Swift had scattered amongst their friends at different periods of life. The avowed motive for this publication, and, in fact, the secret motive, as disclosed in Pope's confidential letters, was to make it impossible thenceforwards for piratical publishers like Curll. Both Pope and Swift dreaded the malice of Curll in case they should die before him. It was one of Curll's regular artifices to publish a heap of trash on the death of any eminent man, under the title of his Remains; and in allusion to that practice it was that Arbuthnot most wittily called Curll "one of the new terrors of death." By publishing *all*, Pope would have disarmed Curll beforehand; and *that* was in fact the purpose; and that plea only could be offered by two grave authors, one forty, the other sixty years old, for reprinting *jeux d'esprit* that never had any other apology than the youth of their authors. Yet, strange to say, after all, some were omitted; and the omission of one opened the door to Curll as well as that of a score. Let Curll have once inserted the narrow end of the wedge, he would soon have driven it home.

This Miscellany, however, in three volumes (published in 1727, but afterwards increased by a fourth in 1732), though in itself a trifling work, had one vast consequence. It drew after it swarms of libels and lampoons, levelled almost exclusively at Pope, although the cipher of the joint authors stood entwined upon the title-page. These libels in *their* turn produced a second re-action; and, by stimulating Pope to effectual anger, eventually drew forth, for the everlasting admiration of posterity, the very greatest of Pope's works; a monument of satirical power the greatest which man has produced, not excepting the MacFleckno of Dryden, namely, the immortal Dunciad.

In October of the year 1727, this poem, in its original form, was completed. Many editions, not spurious altogether, nor surreptitious, but with some connivance, not yet explained, from Pope, were printed in Dublin and in London. But the first quarto and acknowledged edition was published in London early in "1728–9," as the editors choose to write it, that is (without perplexing the reader), in 1729: on March 12 of which year it was presented by the prime minister, Sir Robert Walpole, to the king and queen at St James's.

Like a hornet, who is said to leave his sting in the wound, and afterwards to languish away, Pope felt so greatly exhausted by the efforts connected with the Dunciad (which are far greater, in fact, than all his Homeric labours put together), that he prepared his friends to expect for the future only an indolent companion and a hermit. Events rapidly succeeded which tended to strengthen the impression he had conceived of his own decay, and certainly to increase his disgust with the world. In 1732 died his friend Atterbury; and on December the 7th of the same year Gay, the most unpretending of all the wits whom he knew, and the one with whom he had at one time been domesticated, expired, after an illness of three days, which Dr Arbuthnot declares to have been "the most precipitate" he ever knew. But in fact Gay had long been decaying, from the ignoble vice of too much and too luxurious eating. Six months after this loss, which greatly affected Pope, came the last deadly wound which this life could inflict, in the death of his mother. She had for some time been in her dotage, and recognised no face but that of her son, so that her death was not unexpected; but that circumstance did not soften the blow of separation to Pope. She died on the 7th of June 1733, being then ninety-three years old. Three days after, writing to Richardson the painter for the purpose of urging him to come down and take her portrait before the coffin was closed, he says, "I thank God, her death was as easy as her life was innocent; and as it cost her not a groan, nor even a sigh, there is yet upon her countenance such an expression of tranquillity" that "it would afford the finest image of a saint expired that ever painting drew. Adieu, may you die as happily." The funeral took place on the 11th; Pope then quitted the house, unable to support the silence of her chamber, and did not return for months, nor in fact ever reconciled himself to the sight of her vacant apartment.

Swift also he had virtually lost for ever. In April 1727 this unhappy man had visited Pope for the last time. During this visit occurred the death of George I. Great expectations arose from that event amongst the Tories, in which, of course, Swift shared. It was reckoned upon as a thing of course that Walpole would be dismissed. But this bright gleam of hope proved as treacherous as all before; and the anguish of this final disappointment perhaps it was which brought on a violent attack of Swift's constitutional malady. On the last of August he quitted Pope's house abruptly; concealed himself in London; and finally quitted it, as stealthily as he had before quitted Twickenham, for Ireland, never more to return. He left a most affectionate letter for Pope; but his affliction, and his gloomy anticipations of insanity, were too oppressive to allow of his seeking a personal interview.

Pope might now describe himself pretty nearly as *ultimus suorum;* and if he would have friends in future, he must seek them, as he complains bitterly, almost amongst strangers and another generation. This sense of desolation may account for the acrimony which too much disfigures his writings henceforward. Between 1732 and 1740, he was chiefly engaged in satires, which uniformly speak a high moral tone in the midst of personal invective; or in poems directly philosophical, which almost as uniformly speak the bitter tone of satire in the midst of dispassionate ethics. His Essay on Man was but one link in a general course which he had projected of moral philosophy, here and there pursuing his themes into the fields of metaphysics, but no farther in either field of morals or metaphysics than he could make compatible with a poetical treatment. These works, however, naturally entangled him in feuds of various complexions with people of very various pretensions; and to admirers of Pope so fervent as we profess ourselves, it is painful to acknowledge that the dignity of his latter years, and the becoming tranquillity of increasing age, are sadly disturbed by the petulance and the tone of irritation which, alike to those in the wrong and in the right, inevitably besiege all personal disputes. He was agitated, besides, by a piratical publication of his correspondence. This emanated of course from the den of Curll, the universal robber and "*blatant beast*" of those days; and, besides the injury offered to his feelings by exposing some youthful sallies which he wished to have suppressed, it drew upon him a far more disgraceful imputation, most assuredly unfounded, but accredited by Dr Johnson, and consequently in full currency to this day, of having acted collusively with Curll, or at least through Curll, for the publication of what he wished the world to see, but could not else have devised any decent pretext for exhibiting. The disturbance of his mind on this occasion led to a circular request, dispersed amongst his friends, that they would return his letters. All complied except Swift. He only delayed, and in fact shuffled. But it is easy to read in his evasions, and Pope, in spite of his vexation, read the same tale, viz. that, in consequence of his recurring attacks and increasing misery, he was himself the victim of artifices amongst those who surrounded him. What Pope apprehended happened. The letters were all published in Dublin and in London, the originals being then only returned when they had done their work of exposure.

Such a tenor of life, so constantly fretted by petty wrongs, or by leaden insults, to which only the celebrity of their object lent force or wings, allowed little opportunity to Pope for recalling his powers from angry themes, and converging them upon others of more catholic philosophy. To the last he continued to conceal vipers beneath his flowers; or rather, speaking proportionately to the case, he continued to sheath amongst the gleaming but innocuous lightnings of his departing splendours, the thunderbolts which blasted for ever. His last appearance was his greatest. In 1742 he published the fourth book of the Dunciad; to which it has with much reason been objected, that it stands in no obvious relation to the other three, but which, taken as a separate whole, is by far the most brilliant and the weightiest of his works. Pope was aware of the *hiatus* between this last book and the rest, on which account he sometime called it the greater Dunciad; and it would have been easy for him, with a shallow Warburtonian ingenuity, to invent links that might have satisfied a mere *verbal* sense of connection. But he disdained this puerile expedient. The fact was, and could not be disguised from any penetrating eye, that the poem was not a pursuit of the former subjects; it had arisen spontaneously at various times, by looking at the same general theme of dulness (which, in Pope's sense, includes all aberrations of the intellect, nay, even any defective equilibrium amongst the faculties) under a different angle of observation, and from a different centre. In this closing book, not only bad authors, as in the other three, but all abuses of science or antiquarian knowledge, or connoisseurship in the arts, are attacked: virtuosi, medalists, butterfly-hunters, florists, erring metaphysicians, &c. are all pierced through and through as with the shafts of Apollo. But the imperfect plan of the work as to its internal economy, no less than its exterior relations, is evident in many places; and in particular the whole catastrophe of the poem, if it can be so called, is linked to the rest by a most insufficient incident. To give a closing grandeur to his work, Pope had conceived the idea of representing the earth as lying universally under the incubation of one mighty spirit of dulness; a sort of millennium, as we may call it, for ignorance, error, and stupidity. This would take leave of the reader with effect; but how was it to be introduced? at what era? under what exciting cause? As to the eras, Pope could not settle that; unless it were a *future* era, the description of it could not be delivered as a prophecy; and, not being prophetic, it would want much of its grandeur.

Yet, *as* a part of futurity, how is it connected with our present times? Do they and their pursuits lead to it as a possibility, or as a contingency upon certain habits which we have it in our power to eradicate (in which case this vision of dulness has a *practical* warning), or is it a mere necessity, one amongst the many changes attached to the cycles of human destiny, or which chance brings round with the revolutions of its wheel? All this Pope could not determine; but the exciting cause he *has* determined, and it is preposterously below the effect. The goddess of dulness yawns; and her yawn, which, after all, should rather express the fact and state of universal dulness than its cause, produces a change over all nations tantamount to a long eclipse. Meantime, with all its defects of plan, the poem, as to execution, is superior to all which Pope has done; the composition is much superior to that of the Essay on Man, and more profoundly poetic: the parodies drawn from Milton, as also in the former books, have a beauty and effect which cannot be expressed; and, if a young lady wished to cull for her album a passage from all Pope's writings, which, without a trace of irritation or acrimony, should yet present an exquisite gem of independent beauty, she could not find another passage equal to the little story of the florist and the butterfly-hunter. They plead their cause separately before the throne of dulness; the florist telling how he had reared a superb carnation, which, in honour of the queen, he called Caroline, when his enemy, pursuing a butterfly which settled on the carnation, in securing his own object, had destroyed that of the plaintiff. The defendant replies with equal beauty; and it may certainly be affirmed, that, for brilliancy of colouring and the art of poetical narration, the tale is not surpassed by any in the language.

This was the last effort of Pope worthy of separate notice. He was now decaying rapidly, and sensible of his own decay. His complaint was a dropsy of the chest, and he knew it to be incurable. Under these circumstances, his behaviour was admirably philosophical. He employed himself in revising and burnishing all his later works, as those upon which he wisely relied for his reputation with future generations. In this task he was assisted by Dr Warburton, a new literary friend, who had introduced himself to the favourable notice of Pope about four years before, by a defence of the Essay on Man, which Crousaz had attacked, but in general indirectly and ineffectually, by attacking it through the blunders of a very faulty translation. This poem, however, still labours, to religious readers, under two capital defects. If man, according to Pope, is now so admirably placed in the universal system of things, that evil only could result from any change, then it seems to follow, either that a fall of man is inadmissible; or at least, that, by placing him in his true centre, it had been a blessing universally. The other objection lies in this, that if all is right already, and in this earthly station, then one argument for a future state, as the scene in which evil is to be redressed, seems weakened or undermined.

As the weakness of Pope increased, his nearest friends, Lord Bolingbroke, and a few others, gathered around him. The last scenes were passed almost with ease and tranquillity. He dined in company two days before he died; and on the very day preceding his death he took an airing on Blackheath. A few mornings before he died, he was found very early in his library writing on the immortality of the soul. This was an effort of delirium; and he suffered otherwise from this affection of the brain, and from inability to think in his closing hours. But his humanity and goodness, it was remarked, had survived his intellectual faculties. He died on the 30th of May 1744; and so quietly, that the attendants could not distinguish the exact moment of his dissolution.

We had prepared an account of Pope's quarrels, in which we had shown that, generally, he was not the aggressor; and often was atrociously ill used before he retorted. This service to Pope's memory we had judged important, because it is upon these quarrels chiefly that the erroneous opinion has built itself of Pope's fretfulness and irritability. And this unamiable feature of his nature, together with a proneness to petty manœuvring, are the main foibles that malice has been able to charge upon Pope's moral character. Yet, with no better foundation for their malignity than these doubtful propensities, of which the first perhaps was a constitutional defect, a defect of his temperament rather than his will, and the second has been much exaggerated, many writers have taken upon themselves to treat Pope as a man, if not absolutely unprincipled and without moral sensibility, yet as mean, little-minded, indirect, splenetic, vindictive, and morose. Now the difference between ourselves and these writers is fundamental. They fancy that in Pope's character a basis of ignoble qualities was here and there slightly relieved by a few shining spots; we, on the contrary, believe that in Pope lay a disposition radically noble and generous, clouded and overshadowed by superficial foibles, or, to adopt the distinction of Shakspeare, they see nothing but "dust a little gilt," and we "gold a little dusted." A very rapid glance we will throw over the general outline of his character.

As a friend, it is noticed emphatically by Martha Blount and other contemporaries, who must have had the best means of judging, that no man was so warm hearted, or so much sacrificed himself for others, as Pope; and in fact many of his quarrels grew out of this trait in his character. For once that he levelled his spear in his own quarrel, at least twice he did so on behalf of his insulted parents or his friends. Pope was also noticeable for the duration of his friendships;[1] some dropped him, but he never any throughout his life. And let it be remembered, that amongst Pope's friends were the men of most eminent talents in those days; so that envy at least, or jealousy of rival power, was assuredly no foible of his. In that respect how different from Addison, whose petty manœuvring against Pope proceeded entirely from malignant jealousy. That Addison was more in the wrong even than has generally been supposed, and Pope more thoroughly innocent as well as more generous, we have the means at a proper opportunity of showing decisively. As a son, we need not insist on Pope's pre-eminent goodness. Dean Swift, who had lived for months together at Twickenham, declares that he had not only never witnessed, but had never heard of anything like it. As a Christian, Pope appears in a truly estimable light. He found himself a Roman Catholic by accident of birth; so was his mother; but his father was so upon personal conviction and conversion, yet not without extensive study of the questions at issue. It would have laid open the road to preferment, and preferment was otherwise abundantly before him, if Pope would have gone over to the Protestant faith. And in his conscience he found no obstacle to that change; he was a philosophical Christian, intolerant of nothing but intolerance, a bigot only against bigots. But he remained true to his baptismal profession, partly on a general principle of honour in adhering to a distressed and dishonoured party, but chiefly out of reverence and affection to his mother. In his relation to women, Pope was amiable and gentlemanly; and accordingly was the object of affectionate regard and admiration to many of the most accomplished in that sex. This we mention especially because we would wish to express our full assent to the manly scorn with which Mr Roscoe repels the libellous insinuations against Pope and Miss Martha Blount. A more innocent connection we do not believe ever existed. As an author, Warburton has recorded that no man ever displayed more candour or more docility to criticisms offered in a friendly spirit. Finally, we sum up all in saying, that Pope retained to the last a true and diffusive benignity; that this was the quality which survived all others, notwithstanding the bitter trial which his benignity must have stood through life, and the excitement to a spiteful re-action of feeling which was continually pressed upon him by the scorn and insult which his deformity drew upon him from the unworthy.

---

[1] We may illustrate this feature in the behaviour of Pope to Savage. When all else forsook him, when all beside pleaded the insults of Savage for withdrawing their subscriptions, Pope sent his in advance. And when Savage had insulted *him* also, arrogantly commanding him never "to presume to interfere or meddle in his affairs," dignity and self-respect made Pope obedient to these orders, except when there was an occasion of serving Savage. On his second visit to Bristol (when he returned from Glamorganshire), Savage had been thrown into the jail of the city. One person only interested himself for this hopeless profligate, and was causing an inquiry to be made about his debts at the time Savage died. So much Dr Johnson admits; but he *forgets* to mention the name of this long-suffering friend. *It was Pope.* Meantime, let us not be supposed to believe the lying legend of Savage; he was doubtless no son of Lady Macclesfield's, but an impostor, who would now be sent to the tread-mill.

But the moral character of Pope is of secondary interest: we are concerned with it only as connected with his great intellectual power. There are three errors which seem current upon this subject: *First*, that Pope drew his impulses from French literature; *secondly*, that he was a poet of inferior rank; *thirdly*, that his merit lies in superior "correctness." With respect to the first notion, it has prevailed by turns in every literature. One stage of society, in every nation, brings men of impassioned minds to the contemplation of manners, and of the social affections of man as exhibited in manners. With this propensity co-operates, no doubt, some degree of despondency when looking at the great models of the literature who have usually preoccupied the grander passions, and displayed their movements in the earlier periods of literature. Now it happens that the French, from an extraordinary defect in the higher qualities of passion, have attracted the notice of foreign nations chiefly to that field of their literature in which the taste and the unimpassioned understanding preside. But in all nations such literature is a natural growth of the mind, and would arise equally if the French literature had never existed. The wits of Queen Anne's reign, or even of Charles II.'s, were not French by their taste or their imitation. Butler and Dryden were surely not French; and of Milton we need not speak; as little was Pope French, either by his institution or by his models. Boileau he certainly admired too much; and, for the sake of a poor parallelism with a passage about Greece in Horace, he has falsified history in the most ludicrous manner, without a shadow of countenance from facts, in order to make out that we, like the Romans, received laws of taste from those whom we had conquered. But these are insulated cases and accidents, not to insist on his known and most profound admiration, often expressed, for both Chaucer, and Shakspeare, and Milton. Secondly, that Pope is to be classed as an inferior poet, has arisen purely from a confusion between the departments of poetry which he cultivated and the merit of his culture. The first place must undoubtedly be given for ever,—it cannot be refused,—to the impassioned movements of the tragic, and to the majestic movements of the epic muse. We cannot alter the relations of things out of favour to an individual. But in his own department, whether higher or lower, that man is supreme who has not yet been surpassed; and such a man is Pope. As to the final notion, first started by Walsh, and propagated by Warton, it is the most absurd of all the three; it is not from superior correctness that Pope is esteemed more correct, but because the compass and sweep of his performances lies more within the range of ordinary judgments. Many questions that have been raised upon Milton or Shakspeare, questions relating to so subtile a subject as the flux and reflux of human passion, lie far above the region of ordinary capacities; and the indeterminateness or even carelessness of the judgment is transferred by a common confusion to its objects. But waiving this, let us ask, what is meant by "correctness?" Correctness in what? In developing the thought? In connecting it, or effecting the transitions? In the use of words? In the grammar? In the metre? Under every one of these limitations of the idea, we maintain that Pope is *not* distinguished by correctness; nay, that, as compared with Shakspeare, he is eminently incorrect. Produce us from any drama of Shakspeare one of those leading passages that all men have by heart, and show us any eminent defect in the very sinews of the thought. It is impossible; defects there may be, but they will always be found irrelevant to the main central thought, or to its expression. Now turn to Pope; the first striking passage which offers itself to our memory, is the famous character of Addison, ending thus:

> Who would not laugh, if such a man there be,
> Who but must weep if Atticus were he?

Why must we laugh? Because we find a grotesque assembly of noble and ignoble qualities. Very well; but why then must we weep? Because this assemblage is found actually existing in an eminent man of genius. Well, that is a good reason for weeping; we weep for the degradation of human nature. But then revolves the question, why must we laugh? Because, if the belonging to a man of genius were a sufficient reason for weeping, so much we know from the very first. The very first line says "Peace to all such. But were there one whose fires *true genius kindles* and fair fame inspires." Thus falls to the ground the whole antithesis of this famous character. We are to change our mood from laughter to tears upon a sudden discovery that the character belonged to a man of genius; and this we had already known from the beginning. Match us this prodigious oversight in Shakspeare. Again, take the Essay on Criticism: it is a collection of independent maxims, tied together into a fasciculus by the printer, but having no natural order or logical dependency; generally so vague as to mean nothing: like the general rules of justice, &c. in ethics, to which every man assents; but when the question comes about any practical case, *is* it just? the opinions fly asunder far as the poles. And, what is remarkable, many of the rules are violated by no man so often as by Pope, and by Pope nowhere so often as in this very poem. As a single instance, he proscribes monosyllabic lines; and in no English poem of any pretensions are there so many lines of that class as in this. We have counted above a score, and the last line of all is monosyllabic.

Not therefore for superior correctness, but for qualities the very same as belong to his most distinguished brethren, is Pope to be considered a great poet; for impassioned thinking, powerful description, pathetic reflection, brilliant narration. His characteristic difference is simply that he carried these powers into a different field, and moved chiefly amongst the social paths of men, and viewed their characters as operating through their manners. And our obligations to him arise chiefly on this ground, that having already, in the persons of earlier poets, carried off the palm in all the grander trials of intellectual strength, for the majesty of the epopee and the impassioned vehemence of the tragic drama, to Pope we owe it that we can now claim an equal pre-eminence in the sportive and aërial graces of the mock heroic and satiric muse; that in the Dunciad we possess a peculiar form of satire, in which (according to a plan unattempted by any other nation) we see alternately her festive smile and her gloomiest scowl; that the grave good sense of the nation has here found its brightest mirror; and, finally, that through Pope the cycle of our poetry is perfected and made orbicular, that from that day we might claim the laurel equally, whether for dignity or grace. (w. w. w.)

POPERINGHEN, a large market-town of Belgium, in the province of West Flanders and circle of Ypres. It stands on the river Schipuor, and contains two churches, 1400 houses, and 9080 inhabitants, who are employed in making linen and woollen cloths, and thread-lace, and have several oil mills. It is celebrated for the growth of hops on the land around it, which is a valuable part of its trade.

POPERY, in *Ecclesiastical History*, is regarded by Roman Catholics as a term of reproach, but having been generally received amongst Protestants, now comprehends the religious doctrines and practices adopted and maintained by the church of Rome. The following summary, extracted chiefly from the decrees of the council of Trent, continued under Paul III., Julius III., and Pius IV., by successive sessions, from the year 1545 to 1563, and the creed of Pope Pius IV. subjoined to it, and bearing date November 1564, may not be unacceptable to the reader. One of the fundamental tenets strenuously maintained by Catholic writers, is the infallibility of the church of Rome; and though they are not agreed whether this privilege belongs to the pope or a general council, or to both united, yet they pretend that an infallible living judge is absolutely necessary to determine controversies, and to secure peace, in the Christian church. Protestants, however, allege that the claim of infallibility in any church is not justified by the authority of Scripture, much less does it appertain to the church of Rome; that it is inconsistent with the nature of religion, and the personal obligations of its professors; and that it has proved ineffectual to the end for which it is supposed to have been granted, since popes and councils have disagreed in matters of importance, and, with the advantage of this pretended infallibility, have been incapable of maintaining union and peace. Another essential article of the Catholic creed is the supremacy of the pope, or his sovereign power over the universal church.

Further, the doctrine of the seven sacraments is a peculiar and distinguishing doctrine of the church of Rome. These are baptism, confirmation, the eucharist, penance, extreme unction, holy orders, and matrimony. The council of Trent (sess. vii. can. 1) pronounces an anathema upon those who say that the sacraments are more or fewer than seven, or that any one of the above number is not truly and properly a sacrament. And yet it does not appear that they amounted to this number before the twelfth century, when Hugo de St Victoire and Peter Lombard, about the year 1144, taught that there were seven sacraments. The council of Florence, held in the year 1438, was the first council which determined this number. These sacraments confer grace, according to the decree of the council of Trent (sess. vii. can. 8) *ex opere operato*, that is, by the mere administration of them; three of them, viz. baptism, confirmation, and holy orders, are said (can. 9) to impress an indelible character, so that they cannot be repeated without sacrilege; and the efficacy of every sacrament depends upon the intention of the priest by whom it is administered (can. 11). Pope Pius expressly enjoins that all these sacraments should be administered according to the received and approved rites of the Catholic church. With regard to the eucharist in particular, we may here observe, that the church of Rome holds the doctrine of transubstantiation; the necessity of paying divine worship to Christ under the form of the consecrated bread, or host; and the propitiatory sacrifice of the mass, according to the Catholic ideas of which Christ is truly and properly offered as a sacrifice of propitiation as often as the priest says mass. It likewise practises solitary mass, in which the priest alone consecrates, communicates, and allows communion only in one kind, namely, the bread, to the laity. (Sess. 14.)

The doctrine of merits is another distinguishing tenet of Popery, with regard to which the council of Trent has expressly decreed (sess. vi. can. 32) that the good works of justified persons are truly meritorious, deserving not only an increase of grace, but eternal life, and an increase of glory; and it has anathematized all who deny this doctrine. Of the same kind is the doctrine of satisfaction, which supposes that penitents may truly satisfy, by the afflictions they endure under the dispensations of Providence, or by voluntary penances to which they submit, for the temporary penalties of sin, to which they are subject even after the remission of their eternal punishment. (Sess. vi. can. 30; and sess. xiv. can. 8 and 9.) In this connection we may mention the distinction of venial and mortal sins. The greatest evils arising from the former are the temporary pains of purgatory; but no man, it is said, can obtain the pardon of the latter without confessing to a priest, and performing the penances which he imposes.

The council of Trent (sess. xiv. can. 1) has expressly decreed, that every one is accursed who shall affirm that penance is not truly and properly a sacrament, instituted by Christ in the universal church, for reconciling those Christians to the divine majesty, who have fallen into sin after baptism. And this sacrament, it is declared, consists of two parts, the matter and the form; the matter being the act of the penitent, including contrition, confession, and satisfaction; the form, the act of absolution on the part of the priest. Accordingly it is enjoined, that it is the duty of every man who has fallen after baptism, to confess his sins, once a year at least, to a priest; that this confession is to be secret, for public confession is neither commanded nor expedient; and that it must be exact and particular, including every kind and act of sin, with all the circumstances attending it. When the penitent has so done, the priest pronounces an absolution, which is not conditional or declarative only, but absolute and judicial. This secret or auricular confession was first decreed and established in the fourth council of Lateran, under Pope Innocent III. in 1215 (cap. 21); and the decree of this council was afterwards confirmed and enlarged in the council of Florence and in that of Trent, which ordains, that confession was instituted by Christ, that by the law of God it is necessary to salvation, and that it has always been practised in the Christian church. As for the penances imposed on the penitent by way of satisfaction, they have been commonly the repetition of certain forms of devotion, as paternosters or avemarias, the payment of stipulated sums, pilgrimages, fasts, or various species of corporal discipline. But the most formidable penance, in the estimation of those who belong to the communion of the church of Rome, is the temporary pains of purgatory. Yet under all the penalties which are inflicted or threatened in that church, it has provided relief by its indulgences, and by its prayers or masses for the dead, performed professedly for relieving and rescuing the souls that are detained in purgatory.

Another article which has long been authoritatively enjoined and observed in the church of Rome, is the celibacy of her clergy. This was first enjoined at Rome by Gregory VII. about the year 1074, and established in England by Anselm archbishop of Canterbury about the year 1175; though his predecessor Lanfranc had imposed it upon the prebendaries and clergy who lived in towns. And though the council of Trent was repeatedly petitioned by several princes and states to abolish this restraint, yet the obligation of celibacy was rather established than relaxed by this council; for they decreed, that marriage contracted after a vow of continence is neither lawful nor valid, and thus deprived the church of the possibility of ever restoring marriage to the clergy. If marriage, after a vow, be in itself unlawful, the greatest authority upon earth cannot dispense with it, nor permit marriage to the clergy, who have already vowed continence.

To the doctrines and practices above recited may further be added the worship of images, of which Protestants accuse the Papists. But to this accusation the Papist replies, that he keeps images by him to preserve in his mind the memory of the persons represented by them, as people are wont to preserve the memory of their deceased friends by keeping their pictures. He is taught, he says, to use them so as to cast his eyes upon the pictures or images, and thence to raise his heart to the things represented, and there to employ it in meditation, love, thanksgiving, and desire of imitation, as the object requires. These pictures or images have this advantage, that they inform the mind by one glance, of what in reading might require a whole chapter; there being no other difference between them, than that reading represents leisurely and by degrees, whilst a picture does so at once. Hence he finds a convenience in saying his prayers with some devout pictures before him, the sight of which recalls his wandering thoughts to the right object, and as certainly brings something good into his mind, as an immodest picture disturbs his heart with unclean thoughts. And because he is sensible that these holy pictures and images represent and bring to his mind such objects as in his heart he loves, honours, and venerates, he cannot but on that account love, honour, and respect, the images themselves.[1]

The council of Trent likewise decreed, that all bishops and pastors who have the cure of souls, do diligently instruct their flocks that it is good and profitable to desire the intercession of saints reigning with Christ in heaven. And this decree the Papists endeavour to defend by many arguments. They confess that we have but one Mediator of redemption, but affirm that it is acceptable to God that we should have many mediators of intercession. Moses, say they, was such a mediator for the Israelites; Job for his three friends; Stephen for his persecutors. The Romans were thus desired by St Paul to be his mediators; so were the Corinthians and the Ephesians, so almost every sick man desires the congregation to be his mediators, by remembering him in their prayers. And so, too, the Papist desires the blessed in heaven to be his mediators, that is, that they would pray to God for him. But between these living and dead mediators there is no similarity. The living mediator is present, and certainly hears the request of those who desire him to intercede for them; the dead mediator is as certainly absent, and cannot possibly hear the requests of all those who at the same instant may be begging him to intercede for them, unless he be possessed of the divine attribute of omnipresence; and he who ascribes that attribute to any creature is unquestionably guilty of idolatry. Besides, as this decree is contrary to one of the first principles of natural religion, so it receives no countenance from Scripture, or any Christian writer of the first three centuries. Other practices peculiar to the Papists are the religious honour and respect that they pay to sacred relics, by which they understand not only the bodies and parts of the bodies of the saints, but any of those things that appertained to them, and which they had touched; and the celebration of divine service in an unknown tongue, in regard to which the council of Trent has denounced an anathema on any one who shall say that mass ought to be celebrated only in the vulgar tongue (session xxv. and session xxii. can. 9). Though the council of Lateran under Innocent III. in 1215, had (can. 9) expressly decreed, that as in several parts within the same city and diocese there are many people of different manners and rites mixed together, but of one faith, so the bishops of such cities or dioceses should provide fit men for celebrating divine offices, according to the diversity of tongues and rites, and for administering the sacraments.

We shall only add further, that the church of Rome maintains that unwritten traditions ought to be added to the holy Scriptures, in order to supply their defect, and should be regarded as of equal authority; that the books of the Apocrypha are canonical Scripture; that the vulgate edition of the Bible is to be deemed authentic; and that the Scriptures are to be received and interpreted according to that sense which the holy mother church, to whom it belongs to judge of the true sense, has held, and does hold, and according to the unanimous consent of the Fathers.

Such are the principal and distinguishing doctrines of Catholicism or Popery, most of which have received the sanction of the council of Trent, and that of the creed of Pope Pius IV. which is received, professed, and sworn to by every one who enters into holy orders in the church of Rome, as well as by all proselytes or converts: And at the close of this creed, we are told that the faith contained in it is so absolutely and indispensably necessary, that no man can be saved without it.

POPHAM, Sir John, lord chief justice of the common pleas in the reign of Queen Elizabeth, was the eldest son of Mr Edward Popham of Huntworth, in Somersetshire, and born in the year 1531. He was some time a student of Baliol College, Oxford; "being then," as Anthony Wood says, "given at leisure hours to many sports and exercises." After quitting the university, he established himself in the Middle Temple, where, during his novitiate, he is said to have indulged in that kind of dissipation to which youth and a vigorous constitution more naturally incline, than to the study of voluminous reports; but, satiated at length with what are called the pleasures of the town, he applied sedulously to the study of his profession, was called to the bar, and in 1568 became summer or autumn reader. He was soon afterwards made serjeant at law, and solicitor-general in 1579. In 1581 he was appointed attorney-general, and treasurer of the Middle Temple. In 1592 he was made lord chief justice of the king's bench, and the same year received the honour of knighthood. In the year 1601 his lordship was one of the council detained by the unfortunate Earl of Essex, when he formed the ridiculous project of defending himself in his own house; and, on the earl's trial, Sir John gave evidence against him relative to their detention. He died in the year 1607, aged seventy-six, and was buried in the south aisle of the church at Wellington in Somersetshire, where he generally resided as often as it was in his power to retire. He was thought somewhat severe in the execution of the law against capital offenders; but his severity had the happy effect of reducing the number of highway robberies. He wrote, 1. Reports and cases adjudged in the time of Queen Elizabeth; 2. Resolutions and judgments upon cases and matters agitated in all the courts at Westminster in the latter end of Queen Elizabeth's reign.

POPILIUS, Lænas, Roman ambassador to Antiochus, king of Syria. He was commissioned to order that monarch to desist from hostilities against Ptolemy, king of Egypt, ally of Rome. Antiochus attempted to elude him by evasive answers; but Popilius, with a stick in his hand, made a circle round him in the sand, and charged him, in the name of the Roman senate and people, not to go beyond it till he gave a decisive answer. This boldness intimidated Antiochus, who immediately withdrew his garrisons from Egypt, and desisted from his hostile attempts against Ptolemy.

POPLAR, a parish of the county of Middlesex, in the hundred of Ossulton. It stands on the banks of the river Thames, and was formerly a hamlet in the parish of Stepney. It is extensive, and comprehends the Isle of Dogs, which was formerly a rich marsh, but is now in part converted into docks and canals. The construction of the West India Docks has of late years tended very much to increase the population, which consists chiefly of persons directly or indirectly connected with shipping. In that part of the parish known by the name of Blackwall is the largest private establishment for ship-building in the kingdom. In it there are also many manufactories for rope-making, anchor-forging, and preparing the several other component parts of vessels. There is also a commodious hospital for persons who have been in the service of the East India Company. The population amounted in 1801 to 4493, in 1811 to 7708, in 1821 to 12,223, and in 1831 to 16,849.

---

[1] See Gother's Papist Misrepresented and Represented.

POPO is the name of one of the states comprised in what is denominated the Slave Coast, on the western shores of Africa. In the strictest acceptation, the Slave Coast includes the states of Coto, Popo, Widah, and Ardra, the whole being subject to the king of Dahomey. The maritime flat country here is broader than that of the Gold Coast, and very fertile. The inhabitants are warlike, and addicted to cheating and thieving. This state is divided into the Great and Little Popo. The capital of the former stands on an island at the mouth of a river, which is rendered useless for the navigation of vessels, on account of a formidable bar at its mouth. The capital of Little Popo is situated on the shore near a small river or inlet of the sea. Poultry are here in uncommon abundance; and the flocks of bats are so numerous that they darken the air like dense clouds.

Popo *Isle*, an island or cluster of islands in the Eastern Seas, the chief of which is about fifty miles in circumference. They are distant five leagues from the islands of Bo, and exceed them in height. They are inhabited, and afford a supply of nuts and dried fish. Long. 130. 0. 15. E. Lat. 19. 14. S.

POPOCA, Mount, one of the volcanoes on the summits of the American Cordilleras. Its crater is said to be half a league in circumference.

POPPÆA, Sabina, a Roman matron, daughter of Titus Ollius. She was married and had a son to Rufus Crispinus, a Roman knight. Her beauty captivated Otho, one of Nero's favourites, who carried her off and married her; but he was not long permitted to retain her, for Nero, having heard her extolled for her accomplishments, sent Otho out of Italy, under pretence of presiding over one of the Roman provinces, shortly after which Nero repudiated his wife Octavia, and married Poppæa; but she did not long enjoy the imperial dignity, for Nero soon began to despise her, and treat her with great barbarity. She bore him a son; and when she was again far advanced in pregnancy, he struck her a blow with his foot, of which she died, about 65 A. D. It is said she was so anxious to preserve her beauty, that five hundred she-asses were kept to afford milk, in which she used daily to bathe.

POPULATION.

bject of he article.

THE population of the principal states, of which an account has been given in the course of this work, will be found under their proper heads. The object of this article is to explain the general laws which regulate the increase or decrease of population, and the manner in which they affect the state and condition of human society.

endency f all plants nd animals o increase n a geometrical progression.

In taking a view of animated nature, we cannot fail to be struck with a prodigious power of increase in plants and animals. Their capacity in this respect is indeed almost infinitely various, according with the endless variety of the works of nature, and the different purposes which they seem appointed to fulfil. But, whether they increase slowly or rapidly, if they increase by seed or generation, their natural tendency must be to increase in a geometrical ratio, that is, by multiplication; and at whatever rate they are increasing during any one period, if no further obstacles be opposed to them, they must proceed in a geometrical progression.

In the growth of wheat, a vast quantity of seed is unavoidably lost. When it is dibbled instead of being sown in the common way, two pecks of seed wheat will yield as large a crop as two bushels, and thus quadruple the proportion of the return to the quantity of seed put into the ground. In the Philosophical Transactions for 1768, an account is given of an experiment, in which, by separating the roots obtained from a single grain of wheat, and transplanting them in a favourable soil, a return was obtained of above 500,000 grains. But, without referring to peculiar instances or peculiar modes of cultivation, it is known that calculations have often been made, founded on positive experience, of the produce of wheat in different soils and countries, cultivated in an ordinary way, and making allowance for all ordinary destruction of seed.

Humboldt has collected some estimates of this kind, from which it appears that France, the north of Germany, Poland, and Sweden, taken generally, produce from five to six grains for one; some fertile lands in France produce fifteen for one; and the good lands in Picardy and the Isle of France from eight to ten grains for one. Hungary, Croatia, and Sclavonia, yield from eight to ten grains for one. In the Regno de la Plata, twelve grains for one are produced; near the city of Buenos Ayres, sixteen for one; in the northern part of Mexico seventeen; and in the equinoctial regions of Mexico twenty-four for one.[1]

Now, supposing that in any one country during a certain period, and under the ordinary cultivation, the return of wheat was six grains for one, it would be strictly correct to say that wheat had the capacity of increasing in a geometrical ratio, of such a nature as to sextuple itself every year. And it might safely be calculated hypothetically, that if, setting out from the produce of one acre, land of the same quality could be prepared with sufficient rapidity, and no wheat were consumed, the rate of increase would be such as completely to cover the whole earthy surface of our globe in fourteen years.

In the same manner, if it be found by experience that on land of a certain quality, and making allowance for the ordinary mortality and accidents, sheep will increase on an average so as to double their numbers every two years, it would be strictly correct to say, that sheep have the natural capacity of increasing in a geometrical progression, of which the common multiple is two, and the term two years; and it might safely be said, that if land of the same quality could be provided with sufficient rapidity, and no sheep were consumed, the rate of increase would be such, that if we were to begin with the full number which could be supported on an acre of land, the whole earthy part of the globe might be completely covered with sheep in less than seventy-six years.

If out of this prodigious increase of food, the full support of mankind were deducted, supposing them to increase as fast as they have ever yet increased in any country, the deduction would be comparatively inconsiderable; and the rate of increase would still be enormous, till it was checked, either by the natural want of will on the part of mankind to make efforts for the increase of food beyond what they could possibly consume, or, after a certain period, by their absolute want of power to prepare land of the same quality, so as to allow of the same rate of progress.

Owing to these two causes combined, we see that, notwithstanding this prodigious power of increase in vegetables and animals, their actual increase is extremely slow; and it is obvious, that, owing to the latter cause alone, and long before a final stop was put to all further progress, their actual rate of increase must of necessity be very greatly retarded; as it would be impossible for the most enlightened human efforts to make all the soil of the earth equal in fertility to the average quality of land now in use; while the practicable approaches towards it would require so much time as to occasion, at a very early period, a constant and great check upon what their increase would be if they could exert their natural powers.

---

[1] *Nouvelle Espagne*, liv. iv. c. ix. p. 98.

Elevated as man is above all other animals by his intellectual faculties, it is not to be supposed that the physical laws to which he is subjected should be essentially different from those which are observed to prevail in other parts of animated nature. He may increase slower than most other animals, but food is equally necessary to his support; and if his natural capacity of increase be greater than can be permanently supplied with food from a limited territory, his increase must be constantly retarded by the difficulty of procuring the means of subsistence.

The power of producing food limited by the quantity and nature of the soil.

The main peculiarity which distinguishes man from other animals, in the means of his support, is the power which he possesses of very greatly increasing these means. But this power is obviously limited by the scarcity of land, by the great natural barrenness of a very large part of the surface of the earth, and by the decreasing proportion of produce which must necessarily be obtained from the continual additions of labour and capital applied to land already in cultivation.

It is, however, specifically with this diminishing and limited power of increasing the produce of the soil, that we must compare the natural power of mankind to increase, in order to ascertain whether, in the progress to the full cultivation and peopling of the globe, the natural power of mankind to increase must not of absolute necessity be constantly retarded by the difficulty of procuring the means of subsistence, and if so, what are likely to be the effects of such a state of things.

The natural rate of increase applicable to mankind.

In an endeavour to determine the natural power of mankind to increase, as well as their power of increasing the produce of the soil, we can have no other guide than past experience.

The great check to the increase of plants and animals, we know from experience, is the want of room and nourishment; and this experience would direct us to look for the greatest actual increase of them in those situations where room and nourishment were the most abundant.

On the same principle, we should expect to find the greatest actual increase of population in those situations where, from the abundance of good land, and the manner in which its produce is distributed, the largest portion of the necessaries of life is actually awarded to the mass of the society.

Of the countries with which we are acquainted, the United States of America, formerly the North American colonies of Great Britain, answer most nearly to this description. In the United States not only is there an abundance of good land, but, from the manner in which it has been distributed, and the market which has been opened for its produce, there has been a greater and more constant demand for labour, and a larger portion of necessaries has been awarded to the labourer, than in any of those other countries which possess an equal or greater abundance of land and fertility of soil.

Here, then, we should expect to find that the natural power of mankind to increase, whatever it may be, would be most distinctly marked; and here, in consequence, it appears that the actual rate of the increase of population has been more rapid than in any known country, although, independently of the abundance of good land, and the great demand for labour, it is distinguished by no other circumstances which appear to be peculiarly favourable to the increase of numbers.

It has been stated that all animals, according to the known laws by which they are produced, must have a capacity of increasing in a geometrical progression. And the question with regard to man is, what is the rate of this geometrical progression?

Fortunately, in the country to which we should naturally turn our eyes for an exemplification of the most rapid rate of increase, there have been four enumerations of the people, each at the distance of ten years; and though the estimates of the increase of population in the North American colonies at earlier periods were of sufficient authority, in the absence of more certain documents, to warrant most important inferences, yet as we now possess such documents, and as the period they involve is of sufficient length to establish the point in question, it is no longer necessary to refer to earlier times.

Increase of population in the United States of America

According to a regular census made by order of Congress in 1790, which there is every reason to think is essentially correct, the white population of the United States was found to be 3,164,148. By a similar census in 1800, it was found to have increased to 4,312,841. It had increased, then, during the ten years from 1790 to 1800, at a rate equal to 36·3 per cent., a rate which, if continued, would double the population in twenty-two years and about four months and a half.

According to a third census, in 1810, the white population was found to be 5,862,092,[1] which, compared with the population of 1800, gives an increase in the second ten years at the rate of nearly thirty-six per cent., which, if continued, would double the population in about twenty-two years and a half.

According to the fourth census, in 1820, the white population was found to be 7,861,710,[2] which, compared with the population of 1810, gives an increase in the third ten years at a rate per cent. of 34·1, which, if continued, would double the population in twenty-three years and seven months.

If we compare the period of doubling according to the rate of increase in the most unfavourable ten years of this series, with twenty-five years, we shall find the difference such as fully to cover all the increase of population which would have taken place from emigration.

Amount of emigration.

It appears from a reference to the most authentic documents which can be collected on both sides of the Atlantic, that the emigration to the United States, during the last twenty-five years, falls decidedly short of an average of 10,000 a year. Dr Seybert, the best authority on the other side of the water, states that, from 1790 to 1810, it could not have been so much as 6000 a year. Our official accounts of the number of emigrants to the United States from England, Ireland, and Scotland, during the ten years from 1812 to 1821 inclusive, give an average of less than 7000, although the period includes the extraordinary years 1817 and 1818, in which the emigrations to the United States were much greater than they were ever known to be before or since. The official American accounts, as far as they go, which is only for two years from the 30th September 1819, tend to confirm this average;[1] and, allowing fully for the emigrants from other European countries, the general average will still be under the ten thousand.

---

[1] These numbers are taken from Dr Seybert's Statistical Annals, p. 23.

[2] This number is taken from the American National Calendar for 1822, and has since been compared with the original census as published for the use of the members of Congress.

A new mode was, however, some time ago suggested of estimating the amount of increase in any country derived from emigration.[2] It has been justly stated, that when a census is taken every ten years, and the population is distinguished into those above and those below ten years of age, all above ten years of age, exclusive of emigrants, must have existed in the census immediately preceding, and, consequently, after having made a proper allowance for the mortality during these ten years, the excess above the remaining number must be attributed to emigration. If we had the means of estimating with accuracy the loss which would be sustained in America in ten years by a population not increased by additional births, this mode of estimating the amount of emigration would be unobjectionable, and often very useful.

But unfortunately the means are deficient. Even the annual mortality in the United States is not known. It was supposed by Dr Price (vol. ii. p. 50, 7th edit.) to be one in fifty; by Mr Barton, in the Transactions of the Society at Philadelphia (vol. iii. No. 7), one in forty-five; and it is stated by Mr Bristed, in his work on America and her Resources (p. 20), that the annual deaths average throughout the United States one in forty, in the healthiest districts one in fifty-six, and in the most unhealthy one in thirty-five.

If, however, we could ascertain accurately the average annual mortality, we should still be unable to ascertain the amount of the loss in question; as, under any given law of mortality, it would depend so very much upon the rate at which the population was increasing. The truth of this observation will be placed in a striking light by the following short table, with which we have been favoured by a very able calculator, Mr Milne, author of a well-known Treatise on Annuities and Assurances. It is constructed on the supposition that the population, in each case, is always subject to the same law of mortality as that which prevailed in all Sweden and Finland during the five years ended with 1805, and that the number of births in the present year living in each case is 10,000.

	The Population constantly the same.	The Population increasing in geometrical progression for more than a hundred years, so as to double itself every	
		Fifty Years	Twenty-five Years.
Total population ten years since	393,848	230,005	144,358
Total above ten years of age now	320,495	195,566	126,176
Died during the term of ten years, out of those living at its commencement	73,353	34,439	18,182
Being one of	5·3692	6·6786	7·9396

We see from this table, that under the same law of mortality, the difference of loss sustained in ten years, by a people not increased by fresh births, would in the three cases supposed, of a stationary population, a population doubling in fifty years, and a population doubling in twenty-five years, be as one in 5·3692, one in 6·6786, and one in 7·9396; and that when the population is doubling itself in twenty-five years, the loss would be very little more than one eighth.

But the censuses must be allowed to form a *prima facie* evidence that the population of the United States has, for a considerable time, been going on doubling itself in twenty-five years; and assuming this evidence to be true, which we are warranted in doing till better evidence is produced on the other side, it will appear that the amount of immigration, deduced from the rule here referred to, is less than 10,000 a year.

Thus the white population of the United States in 1800 was 4,312,841.[3] This population, without further accession of births, would in 1810 be diminished one eighth, or reduced to 3,773,736. In 1810 the population above ten years of age was 3,845,389; and, subtracting the former number from the latter, the difference, or amount of emigration, will be 71,653, or 7165 a year.

Again, the white population of 1810 was 5,862,092, which, diminished by one eighth in ten years, would be 5,129,331. The population above ten years of age in 1820 was 5,235,940.[4] Subtracting the former from the latter, the difference, or amount of emigration, is 106,608, or 10,660 a year; showing, as we should expect, a greater amount of emigration from 1810 to 1820 than from 1800 to 1810, but, even in the latter ten years, and including emigrations from Canada, as well as all other countries, little exceeding 10,000.

Altogether, then, we can hardly err in defect, if we allow 10,000 a year for the average increase from emigration during the twenty-five years from 1795 to 1820; and applying this number to the slowest period of increase, when the rate was such as to double the population in twenty-three years and seven months, it may be easily calculated, that in the additional year and five months a population of 5,862,000 would have increased to an amount much more than sufficient to cover an annual emigration of 10,000 persons, with the increase from them at the same rate.

Such an increase from them, however, would not take place. It appears from an account in the National Calendar of the United States for the year 1821, that of the 7001 persons who had arrived in America from the 30th of September 1819 to the 30th of September 1820, 1959 only were females, and the rest, 5042, were males; a proportion which, if it approaches towards representing the average, must very greatly reduce the number from which any increase ought to be calculated.

If, however, we omit these considerations; if we suppose a yearly emigration from Europe to America of 10,000 persons for the twenty-five years from 1795 to 1820, the greatest part of which time Europe was involved in a most extensive scene of warfare, requiring all its population; and further, if we allow for an increase of all the emigrants during the *whole period*, at the fullest rate; the remaining numbers will still be sufficient to show a doubling of the population in less than twenty-five years.

The white population of 1790 was 3,164,148. This population, according to the rate at which it was increasing, would have amounted to about 3,694,100 in 1795; and supposing it to have just doubled itself in the twenty-five years from 1795 to 1820, the population in 1820 would have been 7,388,200. But the actual white population of 1820 appears, by the census then taken, to be 7,861,710, showing an excess of 473,510; whereas an emigration of 10,000 persons annually, with the increase from them at three per cent., a rate which would double a population in less than twenty-four years, would only amount to 364,592.

---

[2] This mode was suggested by Mr Booth, in Mr Godwin's Answer to Mr Malthus.

[3] Seybert's Statistical Annals, p. 23.

[4] American National Calendar for 1822, p. 246.

But the most striking confirmation of the censuses of the United States, and the most remarkable proof of the rate of increase being occasioned almost exclusively by procreation, have been furnished to us by Mr Milne. In his work on Annuities and Assurances, which contains much valuable and interesting information on the subject of population, he had noticed the effects of the frequent pressure of want on the labouring classes of Sweden, which, by increasing the proportion of deaths, rendered the law of mortality so accurately observed in that country by Professors Wargentin and Nicander inapplicable to other countries more favourably circumstanced. But the law of mortality was observed to be gradually improving from the time that Dr Price constructed his Swedish table; and the period from 1800 to the end of 1805 was so free from scarcities and epidemics, and the healthiness of the country had been further so much improved by the introduction of vaccination, that he justly thought the law of mortality, as observed during these five years, might suit countries where the condition of the people was known to be much better than it had generally been in Sweden. On these grounds he applied the Swedish law of mortality, during the term mentioned, to the hypothesis of a population which had been increasing by procreation, in geometrical progression, for more than a hundred years, so as to double every twenty-five years. Assuming this population to be one million, he distributed it, by a process well known to persons conversant with these subjects, into the different ages referred to in the American censuses, and then compared them with the same number of persons distributed according to the actual returns of the ages in the American censuses for the three periods of 1800, 1810, and 1820. The results are as follows:

Distribution of a Population of 1,000,000 *Persons in the under-mentioned intervals of Age.*

Between the Ages of	According to			
		United States.		
	The Hypothesis.	Census of 1800.	Census of 1810.	Census of 1820.
0 and 10	337,592	334,556	344,024	333,995
10 and 16	145,583	154,898	156,345	154,913
16 and 26	186,222	185,046	189,227	198,114
26 and 45	213,013	205,289	190,461	191,139
45 and 100	117,590	120,211	119,943	121,839
0 and 100	1,000,000	1,000,000	1,000,000	1,000,000
Under 16	483,175	489,454	500,369	488,908
Above 16	516,825	510,546	499,631	511,092

The general resemblance in the distribution of the ages in the three different censuses to each other, and to the hypothesis, clearly proves,

1*st*, That the distribution of the ages in the different enumerations must be made with some care, and may, therefore, be relied on as in the main correct.

2*dly*, That the law of mortality assumed in the hypothesis cannot deviate essentially from the law of mortality which prevails in the United States; and,

3*dly*, That the actual structure of the American population differs very little from what it would be if it were increasing regularly from procreation only, in geometrical progression, so as to double itself every twenty-five years; and that we may, therefore, safely infer that it has been very little disturbed by immigration.

If to these proofs of the rapid increase of population which has actually taken place, we add the consideration that this rate of increase is an average applying to a most extensive territory, some parts of which are known to be unhealthy; that some of the towns of the United States are now large; that many of the inhabitants must be engaged in unwholesome occupations, and exposed to many of those checks to increase which prevail in other countries; and further, that in the western territories, where these checks do not occur, the rate of increase is beyond comparison more rapid than the general average, after making the fullest allowance for immigration; it must appear certain, that the rate at which the population of the whole of the United States has actually increased for the last thirty years must fall very decidedly short of the actual capacity of mankind to increase under the most favourable circumstances.

The rate of increase in the United States confirmed by that of other countries.

The best proof that can be obtained of the capacity of mankind to increase at a certain rate, is their having really increased at that rate. At the same time, if any peculiarly rapid increase which had appeared to take place in a particular country were quite unsupported by other evidence, we might be disposed to attribute it to error or accident, and might scarcely be justified in founding important conclusions upon it. But this is far from being the case in the present instance. The rate of increase which has at times taken place in other countries, under the operation of great and obvious checks to the progress of population, sufficiently shows what might be expected if these checks were removed.

Increase of population in New Spain.

The countries most resembling the United States of America are those territories of the new world which lately belonged to Spain. In abundance and fertility of soil they are indeed superior; but almost all the vices in the government of the mother country were introduced into her colonial possessions, and particularly that very unequal distribution of landed property which takes place under the feudal system. These evils, and the circumstance of a very large part of the population being Indians in a depressed state, and inferior in industry and energy to Europeans, necessarily prevent that rapid increase of numbers which the abundance and fertility of the land would admit of. But it appears, from the instructive and interesting account of New Spain which M. Humboldt has not long since given to the public, that for the last half of the eighteenth century the excess of the births above the deaths, and the progress of the population, have been very great. The following are the proportions of burials to baptisms in the registers of eleven villages, the details of which were communicated to M. Humboldt by the curates.

	Burials.	Baptisms.
At Dolores	100	253
Singuilucan	100	234
Calymaya	100	202
Guanaxuato	100	201
St Anne	100	195
Marsil	100	194
Queretaro	100	188
Axapuzco	100	157
Yguala	100	140
Malacatepec	100	130
Panuco	100	123

The mean proportion is 100 to 183.

But the proportion which M. Humboldt considers as best suited to the whole of the population is 100 to 170.

In some of the villages above mentioned, the proportion of the births to the population is extraordinarily great, and the proportion of deaths very considerable; showing, in a striking point of view, the early marriages and early deaths of a tropical climate, and the more rapid passing away of each generation.[1]

At Queretaro, it appears that the baptisms were to the population as one to fourteen, and the burials as one to twenty-six.

At Guanaxuato, including the neighbouring mines of St Anne and of Marsil, the baptisms were to the population as one to fifteen, and the burials as one to twenty-nine.

The general result from all the information which could be collected was, that the proportion of births to the population, for the whole of the kingdom of New Spain, was as one to seventeen, and of the deaths as one to thirty. These proportions of births to deaths, if they were continued, would double the population in twenty-seven and a half years.

M. Humboldt further observes, that the information which he had collected respecting the proportions of the births to the deaths, and of these to the whole population, proves, that if the order of nature were not interrupted by some extraordinary and disturbing causes, the population of New Spain ought to double itself every nineteen years.[2]

It is known, however, that these causes do occur in the actual state of things; consequently we cannot consider the actual rate of the increase of population in New Spain as greater than according to the former calculation. But a rate of increase such as to double the population in twenty-seven and a half years, in spite of all the obstacles enumerated by M. Humboldt, is very extraordinary. It is next to the increase of the United States, and greatly superior to any that can be found in Europe.

Yet in Europe, the tendency to increase is always very strongly marked, and the actual increase for periods of some length is sometimes much greater than could be expected beforehand, considering the obstacles to be overcome.

It appears from Sussmilch,[3] that the population of Prussia and Lithuania, after the great plague in 1709 and 1710, doubled itself in about forty-four years, from the excess of the births above the deaths enumerated in the registers.

In Russia, the whole population in 1763 was estimated, by enumeration and calculation, at twenty millions, and in 1796 at thirty-six millions.[4] This is a rate of increase which would occasion a doubling in less than forty-two years.

In 1695, the population of Ireland was estimated at 1,034,000. According to the returns in 1821, it had increased to the prodigious amount of 6,846,949;[5] and it is thought that when the deficiencies have been supplied by the final returns of the enumerators, it will be upwards of seven millions. This is an example of an actual increase for 125 years together, at a rate which would double the population in about forty-five years; and this has taken place under the frequent pressure of great distress among the labouring classes of society, and the practice of frequent and considerable emigration.

But for the proof of the power of population to increase under great obstacles of the preventive, as well as of the positive kind, we need not go out of Great Britain. The rate of increase since our enumerations have commenced has been very remarkable for a country which was considered as well peopled before, and some of the details accompanying the returns tend strikingly to illustrate the principle of population.

Increase of population in Great Britain from 1800 to 1821.

The population of Great Britain, according to the enumerations of 1821 and 1811, was, respectively, 10,942,646 and 12,596,803.[6] This is a rate of increase, during the ten years, of rather above fifteen per cent., a rate which, if continued, would double the population in between forty-nine and fifty years.

By the enumeration of 1821, it appears that the population was 14,391,631,[7] which, compared with the population of 1811, gives a rate of increase during the ten years of 14·25 per cent., a rate which would double the population in about fifty-two years.

According to these numbers, the rate of increase during the last ten years was slower than that of the first; but it appears, from the excess of the number of males above females in the enumeration of 1811, so opposite to the state of the population in 1801 and 1821, when the females exceeded the males, particularly at the latter period, that of the large number added to the population for the army, navy, and registered merchant ships in 1811, a considerable proportion must have been foreigners. On this account, and on account of the further difficulty of knowing what part of this number might properly belong to Ireland, it has been proposed to estimate the rate per cent. at which the population has increased in each of the ten years by the females only; and, according to this mode of computation, the population increased during the first period at the rate of 14·02 per cent., and during the second at the rate of 15·82. (Preliminary Observations, p. 8.) This last rate of increase would double the population in less than forty-eight years.

The only objection to this mode of computation is, that it does not take into consideration the greater destruction of the males during the war. In 1801, the females exceeded the half of the population by 21,031, and in 1821 by 63,890, while, at the intermediate period, owing to the causes above mentioned, the females fell short of the half of the males by 35,685.

When, however, a proper distribution has been made of the army and navy among the resident population, and taking England and Wales alone, it appears that from 1801 to 1811 the population increased at the rate of fourteen and a half per cent., and from 1811 to 1821, at the rate of sixteen and one third per cent. (Preliminary Observations, p. 32.) At the former of these rates, the period of doubling would be rather above fifty years; at the latter, under forty-six years; and, taking the whole period, the time of doubling would be about forty-eight years. Yet in Great Britain there is a much larger proportion of the population living in towns, and engaged in occupations considered as unhealthy, than in any other known country of the same extent. There are also the best reasons for believing that in no other country of the same extent is there to be found so great a proportion of late marriages, or so great a proportion of persons remaining unmarried, as in Great Britain. It is further known that the number of emigrants from Great Britain greatly exceed those who come into the country. And if, under these circumstances, a demand for labour and an increase of the funds for its maintenance could for twenty years together occasion such a rate of increase as, if continued, would double the population in forty-eight years, and quadruple it in ninety-six years, it is in the highest degree probable, that if the encouragements to marriage and the means of supporting a family were as great as in America, the period of doubling in Great Britain would not be more than twenty-five years, even in spite of her great towns and manufactories; and would be decidedly less if these obstacles were removed.

---

[1] The details which M. Humboldt has given of the population of New Spain are highly interesting, as they are the first of any consequence which the public has yet received of a tropical climate. The peculiarities which mark them are exactly of the kind which might have been expected, though the proportion of births is still greater than we could have ventured to suppose.

[7] Ibid.

The lowest rate of increase that can be assumed for the natural progress of population.

Taking therefore into consideration the actual rate of increase which appears from the best documents to have taken place over a very large extent of country in the United States of America, very variously circumstanced as to healthiness and rapidity of progress; considering, further, the rate of increase which has taken place in New Spain, and also in many countries of Europe, where the means of supporting a family, and other circumstances favourable to increase, bear no comparison with those of the United States; and adverting particularly to the great increase of population which has taken place in this country during the last twenty years, under the formidable obstacles to its progress which must press themselves upon the attention of the most careless observer; it must appear, that the assumption of a rate of increase such as would double the population in twenty-five years, as representing the natural progress of population, when not checked by the difficulty of procuring the means of subsistence, or other peculiar causes of premature mortality, must be very decidedly within the truth.

It may be safely asserted, therefore, that population, when unchecked, increases in a geometrical progression of such a nature as to double itself every twenty-five years.

Different character of the rate of increase in the food of a limited territory.

It would be unquestionably desirable to have the means of comparing the natural rate of the increase of population when unchecked, with the possible rate of the increase of food, in a limited territory, such as that in which man is actually placed; but the latter estimate is much more difficult and uncertain than the former. If the rate of the increase of population at a particular period of some little extent can be ascertained with tolerable exactness, we have only to suppose the continuance of the same encouragements to marriage, the same facility of supporting a family, the same moral habits, with the same rate of mortality; and the increase of the population at the same rate, after it had reached a thousand millions, would be just as probable as at any intermediate and earlier period; but it is quite obvious that the increase of food in a limited space must proceed upon a principle totally different. It has been already stated, that while land of good quality is in great abundance, the rate at which food might be made to increase would far exceed what is necessary to keep pace with the most rapid increase of population which the laws of nature in relation to human kind permit. But if society were so constituted as to give the fullest scope possible to the progress of cultivation and population, all such lands, and all lands of moderate quality, would soon be occupied; and when the future increase of the supply of food came to depend upon the taking of very poor land into cultivation, and the gradual and laborious improvement of the land already cultivated, the rate of the increase of food would certainly have a greater resemblance to a decreasing geometrical ratio than an increasing one. The yearly increment of food would, at any rate, have a constant tendency to diminish, and the amount of the increase of each successive ten years would probably be less than that of the preceding.

Practically, however, great uncertainty must take place. An unfavourable distribution of produce, by prematurely diminishing the demand for labour, might retard the increase of food at an early period, in the same manner as if cultivation and population had been further advanced; while improvements in agriculture, accompanied by a great demand for labour and produce, might for some time occasion a rapid increase of food and population at a later period, in the same manner as if cultivation and population had been in an earlier stage of their progress. These variations, however, obviously arise from causes which do not impeach the general tendency of a continued increase of produce in a limited territory to diminish the power of its increase in future.

Supposition respecting the power of increasing food.

Under this certainty with regard to the general tendency, and uncertainty in reference to particular periods, it must be allowable, if it throws light on the subject, to make a supposition respecting the increase of food in a limited territory, which, without pretending to accuracy, is clearly more favourable to the power of the soil to produce the means of subsistence for an increasing population, than any experience which we have of its qualities will warrant.

If, setting out from a tolerably well-peopled country, such as England, France, Italy, or Germany, we were to suppose that, by great attention to agriculture, its produce could be permanently increased every twenty-five years by a quantity equal to that which it at present produces, it would be allowing a rate of increase decidedly beyond any probability of realization. The most sanguine cultivators could hardly expect that, in the course of the next two hundred years, each farm in this country on an average would produce eight times as much food as it produces at present, and still less that this rate of increase could continue, so that each farm would produce twenty times as much as at present in five hundred years, and forty times as much in a thousand years. Yet this would be but an arithmetical progression, and would fall short, beyond all comparison, of the natural increase of population in a geometrical progression, according to which the inhabitants of any country, in five hundred years, instead of increasing to twenty times, would increase to above a million times their present numbers.

It will be said, perhaps, that many parts of the earth are as yet very thinly peopled, and, under proper management, would allow of a much more rapid increase of food than would be possible in the more fully inhabited states of Europe. This is unquestionably true. Some parts of the earth would no doubt be capable of producing food at such a rate as to keep pace for a few periods with an unrestricted increase of population. But to put this capacity fully into action, is of all things the most difficult. If it is to be accomplished by the improvement of the actual inhabitants of the different parts of the earth in knowledge, in government, in industry, in arts, and in morals, it is scarcely possible to say how it ought to be commenced with the best prospect of success, or to form a conjecture as to the time in which it could be effected.

Insufficiency of emigration.

If it is to be accomplished by emigration from the more improved parts of the world, it is obvious that it must involve much war and extermination; besides all the difficulties usually attendant upon new settlements in uncivilized countries; and these alone are so formidable, and for a long time so destructive, that, combined with the unwillingness which people must always naturally feel to quit their own country, much distress would be suffered at home before relief would be sought for in emigration.

But, supposing for a moment that the object could be fully accomplished, that is, supposing that the capacity of the earth to produce the necessaries of life could be put fully into action, and that they were distributed in the proportions most favourable for the growth of capital and the effective demand for labour, the increase of population, whether arising from the increase of the inhabitants of each country, or from emigrants issuing from all those countries which were more advanced in cultivation, would be so rapid, that, in a period comparatively quite short, all the good lands would be occupied, and the rate of the possible increase of food would be reduced much below the arithmetical ratio above supposed.

If, merely during the short period which has elapsed since our Revolution of 1688, the population of the earth had increased at its natural rate when unchecked, supposing the number of people at that time to have been only eight hundred millions, all the land of the globe, without making allowance for deserts, forests, rocks, and lakes, would on an average be equally populous with England and Wales at present. This would be accomplished in five doublings, or a hundred and twenty-five years; and one or two doublings more, or a period less than that which has elapsed since the beginning of the reign of James I., would produce the same effect from the overflowings of the inhabitants of those countries where, owing to the further progress of cultivation, the soil had not the capacity of producing food so as to keep pace with the increase of an unrestricted population.

Whatever temporary and partial relief, therefore, may be derived from emigration by particular countries in the actual state of things, it is quite obvious, that, considering the subject generally and largely, emigration may be fairly said not in any degree to touch the difficulty. And, whether we exclude or include emigration, whether we refer to particular countries, or to the whole earth, the supposition of a future capacity in the soil to increase the necessaries of life every twenty-five years by a quantity equal to that which is at present produced, must be decidedly beyond the truth.

Effect of the two different rates of increase when brought together.

But if the natural increase of population, when unchecked by the difficulty of procuring the means of subsistence, or other peculiar causes, be such as to continue doubling its numbers in twenty-five years; and the greatest increase of food, which, for a continuance, could possibly take place on a limited territory like our earth in its present state, be at the most only such as would add every twenty-five years an amount equal to its present produce; it is quite clear that a powerful check on the increase of population must be almost constantly in action.

By the laws of nature man cannot live without food. Whatever may be the rate at which population would increase if unchecked, it never can actually increase in any country beyond the food necessary to support it. But, by the laws of nature in respect to the powers of a limited territory, the additions which can be made in equal periods to the food which it produces must, after a short time, either be constantly decreasing, which is what would really take place; or, at the very most, must remain stationary, so as to increase the means of subsistence only in an arithmetical progression. Consequently, it follows necessarily that the average rate of the *actual* increase of population over the greatest part of the globe, obeying the same laws as the increase of food, must be totally of a different character from the rate at which it would increase if *unchecked*.

The great question, then, which remains to be considered, is the manner in which this constant and necessary check upon population practically operates.

General character of the checks to population.

If the soil of any extensive well-peopled country were equally divided amongst its inhabitants, the check would assume its most obvious and simple form. Perhaps each farm in the well-peopled countries of Europe might allow of one, or even two doublings, without much distress, but the absolute impossibility of going on at the same rate is too glaring to escape the most careless thinker. When, by extraordinary efforts, provision had been made for four times the number of persons which the land can support at present, what possible hope could there be of doubling the provision in the next twenty-five years?

Yet there is no reason whatever to suppose that any thing besides the difficulty of procuring in adequate plenty the necessaries of life, should either indispose this greater number of persons to marry early, or disable them from rearing in health the largest families. But this difficulty would of necessity occur, and its effect would be either to discourage early marriages, which would check the rate of increase by preventing the same proportion of births; or to render the children unhealthy from bad and insufficient nourishment, which would check the rate of increase by occasioning a greater proportion of deaths; or, what is most likely to happen, the rate of increase would be checked, partly by the diminution of births, and partly by the increase of mortality.

The first of these checks may, with propriety, be called the *preventive check* to population; the second, the *positive check;* and the absolute necessity of their operation in the case supposed is as certain and obvious as that man cannot live without food.

Taking a single farm only into consideration, no man would have the hardihood to assert that its produce could be made permanently to keep pace with a population increasing at such a rate as it is observed to do for twenty or thirty years together at particular times and in particular countries. He would, indeed, be compelled to acknowledge, that if, with a view to allow for the most sanguine speculations, it has been supposed that the additions made to the necessaries produced by the soil in given times might remain constant, yet that this rate of the increase of produce could not possibly be realized; and that, if the capacity of the soil were at all times put properly into action, the additions to the produce would, after a short time, and independently of new inventions, be constantly decreasing, till, in no very long period, the exertions of an additional labourer would not produce his own subsistence.

But what is true in this respect in reference to a single farm, must necessarily be true of the whole earth, from which the necessaries of life for the actual population are derived. And what would be true in respect to the checks to population if the soil of the earth were equally divided among the different families which inhabit it, must be true under the present unequal division of property and variety of occupations. Nothing but the confusion and indistinctness arising from the largeness of the subject, and the vague and false notions which prevail respecting the efficacy of emigration, could make persons deny in the case of an extensive territory or the whole earth, what they could not fail to acknowledge in the case of a single farm, which may be said fairly to represent it.

It may be expected, indeed, that in civilized and improved countries the accumulation of capital, the division of labour, and the invention of machinery, will extend the bounds of production; but we know from experience that the effects of these causes, which are quite astonishing in reference to some of the conveniences and luxuries of life, are very much less efficient in producing an increase of food; and although the saving of labour and an improved system of husbandry may be the means of pushing cultivation upon much poorer lands than could otherwise be worked, yet the increased quantity of the necessaries of life so obtained can never be such as to supersede, for any length of time, the operation of the preventive and positive checks to population. And not only are these checks as absolutely necessary in civilized and improved countries, as they would be if each family had a certain portion of land allotted to it, but they operate almost exactly in the same way. The distress which would obviously arise in the most simple state of society, from the natural tendency of population to increase faster than the means of subsistence in a limited territory, is brought home to the higher classes of an improved and populous country, in the difficulty which they find in supporting their families in the same rank of life with themselves; and to the labouring classes, which form the great mass of society, in the insufficiency of the real wages of common labour to bring up a large family.

If in any country the yearly earnings of the commonest labourers, determined, as they always will be, by the state of the demand and the supply of necessaries compared with labour, be not sufficient to bring up in health the largest families, one of the three things before stated must happen; either the prospect of this difficulty will prevent some and delay other marriages; or the diseases arising from bad nourishment will be introduced, and the mortality be increased; or the progress of population will be retarded, partly by one cause and partly by the other.

Of the effect of private property on the progress of population.

According to all past experience, and the best observations which can be made on the motives which operate upon the human mind, there can be no well-founded hope of obtaining a large produce from the soil, but under a system of private property. It seems perfectly visionary to suppose that any stimulus short of that which is excited in man by the desire of providing for himself and family, and of bettering his condition in life, should operate on the mass of society with sufficient force and constancy to overcome the natural indolence of mankind. All the attempts which have been made since the commencement of authentic history to proceed upon a principle of common property, have either been so insignificant that no inference can be drawn from them, or have been marked by the most signal failures; and the changes which have been effected in modern times by education do not seem to advance a single step towards making such a state of things more probable in future. We may therefore safely conclude, that while man retains the same physical and moral constitution which he is observed to possess at present, no other than a system of private property stands the least chance of providing for such a large and increasing population as that which is to be found in many countries at present.

But though there is scarcely any conclusion which seems more completely established by experience than this, yet it is unquestionably true that the laws of private property, which are the grand stimulants to production, do themselves so limit it, as always to make the actual produce of the earth fall very considerably short of the *power* of production. On a system of private property no adequate motive to the extension of cultivation can exist, unless the returns are sufficient, not only to pay the wages necessary to keep up the population, which, at the least, must include the support of a wife and two or three children, but also afford a profit on the capital which has been employed. This necessarily excludes from cultivation a considerable portion of land, which might be made to bear corn. If it were possible to suppose that man might be adequately stimulated to labour under a system of common property, such land might be cultivated, and the production of food and the increase of population might go on, till the soil absolutely refused to grow a single additional quarter, and the whole of the society was exclusively engaged in procuring the necessaries of life. But it is quite obvious that such a state of things would inevitably lead to the greatest degree of distress and degradation. And if a system of private property secures mankind from such evils, which it certainly does in a great degree, by securing to a portion of the society the leisure necessary for the progress of the arts and sciences, it must be allowed that such a check to the increase of cultivation confers on society a most signal benefit.

But it must perhaps also be allowed, that, under a system of private property, cultivation is sometimes checked in a degree and at a period not required by the interest of society. And this is particularly likely to happen when the original divisions of land have been extremely unequal, and the laws have not given sufficient facility to a better distribution of them. Under a system of private property, the only effectual demand for produce must come from the owners of property; and though it be true that the effectual demand of the society, whatever it may be, is best supplied under the most perfect system of liberty, yet it is not true that the tastes and wants of the effective demanders are always, and necessarily, the most favourable to the progress of national wealth. A taste for hunting and the preservation of game among the owners of the soil will, without fail, be supplied, if things be allowed to take their natural course; but such a supply, from the manner in which it must be effected, would inevitably be most unfavourable to the increase of produce and population. In the same manner, the want of an adequate taste for the consumption of manufactured commodities among the possessors of surplus produce, if not fully compensated by a great desire for personal attendance, which it never is, would infallibly occasion a premature slackness in the demand for labour and produce, a premature fall of profits, and a check to cultivation.

It makes little difference in the actual rate of the increase of population, or the necessary existence of checks to it, whether that state of demand and supply which occasions an insufficiency of wages to the whole of the labouring classes be produced prematurely by a bad structure of society and an unfavourable distribution of wealth, or necessarily by the comparative exhaustion of the soil. The labourer feels the difficulty nearly in the same degree, and it must have nearly the same results, from whatever cause it arises; consequently, in every country with which we are acquainted, where the yearly earnings of the labouring classes are not sufficient to bring up in health the largest families, it may be safely said that population is actually checked by the difficulty of procuring the means of subsistence. And, as we well know that ample wages, combined with full employment for all who choose to work, are extremely rare, and scarcely ever occur, except for a certain time, when the knowledge and industry of an old country is applied, under favourable circumstances, to a new one; it follows that the pressure arising from the difficulty of procuring subsistence is not to be considered as a remote one, which will be felt only when the earth refuses to produce any more, but as one which not only actually exists at present over the greatest part of the globe, but, with few exceptions, has been almost constantly acting upon all the countries of which we have any account.

It is unquestionably true, that, in no country of the globe have the government, the distribution of property, and the habits of the people, been such as to call forth, in the most effective manner, the resources of the soil. Consequently, if the most advantageous possible change in all these respects could be supposed at once to take place, it is certain that the demand for labour and the encouragement to production might be such as for a short time in some countries, and for rather a longer in others, to lessen the operation of the checks to population which have been described. It is specifically this truth constantly obtruding itself upon our attention which is the great source of delusion on this subject, and creates the belief that man could always produce from the soil much more than sufficient to support himself and family. In the actual state of things this power has perhaps always been possessed. But for it we are indebted wholly to the ignorance and bad government of our ancestors. If they had properly called forth the resources of the soil, it is quite certain that we should now have but scanty means left of further increasing our food. If merely since the time of William the Conqueror all the nations of the earth had been well governed, and if the distribution of property, and the habits both of the rich and the poor, had been the most favourable to the demand for produce and labour, though the amount of food and population would have been prodigiously greater than at present, the means of diminishing the checks to population would unquestionably be less. That difficulty in procuring the necessaries of life which is now felt in the comparatively low wages of labour almost all over the world, and is occasioned partly by the necessary state of the soil, and partly by a premature check to the demand for produce and labour, would then be felt in a greater degree, and would less admit of any relaxation in the checks to population, because it would be occasioned wholly and necessarily by the state of the soil.

The laws f nature esponsible or the necessity of hecks to opulation.

It appears, then, that what may be called the proportionate amount of the necessary checks to population depends very little upon the efforts of man in the cultivation of the soil. If these efforts had been directed from the first in the most enlightened and efficient manner, the checks necessary to keep the population on a level with the means of subsistence, so far from being lightened, would in all probability be operating with greater force; and the condition of the labouring classes, so far as it depends on the facility of procuring the means of subsistence, instead of being improved, would in all probability be deteriorated.

It is to the laws of nature, therefore, and not to the conduct and institutions of man, that we are to attribute the necessity of a strong check on the natural increase of population.

Man reponsible or the revailing haracter f these hecks.

But though the laws of nature which determine the rate at which population would increase if unchecked, and the very different rate at which the food required to support population could be made to increase in a limited territory, are undoubtedly the causes which render necessary the existence of some great and constant check to population, yet a vast mass of responsibility remains behind on man and the institutions of society.

In the first place, they are certainly responsible for the present scanty population of the earth. There are few large countries, however advanced in improvement, the population of which might not have been doubled or tripled, and there are many which might be ten, or even a hundred times as populous, and yet all the inhabitants be as well provided for as they are now, if the institutions of society and the moral habits of the people had been for some hundred years the most favourable to the increase of capital, and the demand for produce and labour.

Secondly, though man has but a trifling and temporary influence in altering the proportionate amount of the checks to population, or the degree in which they press upon the actual numbers, yet he has a great and most extensive influence on their character and mode of operation.

It is not in superseding the necessity of checks to population, in the progress of mankind to the full peopling of the earth (which may with truth be said to be a physical impossibility), but in directing these checks in such a way as to be the least prejudicial to the virtue and happiness of society, that government and human institutions produce their great effect. Here we know, from constant experience, that they have great power. Yet even here it must be allowed that the power of government is rather indirect than direct, as the object to be attained depends mainly upon such a conduct on the part of individuals as can seldom be directly enforced by laws, though it may be powerfully influenced by them.

This will appear if we consider more particularly the nature of those checks which have been classed under the general heads of Preventive and Positive.

It will be found that they are all resolvable into *moral restraint*, *vice*, and *misery*. And if, from the laws of nature, some check to the increase of population be absolutely inevitable, and human institutions have any influence upon the extent to which each of these checks operates, a heavy responsibility will be incurred, if all that influence, whether direct or indirect, be not exerted to diminish the amount of vice and misery.

These checks resolvable into moral restraint, vice, and misery.

Moral restraint, in application to the present subject, may be defined to be, abstinence from marriage, either for a time or permanently, from prudential considerations, with a strictly moral conduct towards the sex in the interval. And this is the only mode of keeping population on a level with the means of subsistence, which is perfectly consistent with virtue and happiness. All other checks, whether of the preventive or the positive kind, though they may greatly vary in degree, resolve themselves into some form of vice or misery.

The remaining checks of the preventive kind, are the sort of intercourse which renders some of the women of large towns unprolific; a general corruption of morals with regard to the sex, which has a similar effect; unnatural passions, and improper arts to prevent the consequences of irregular connections. These evidently come under the head of vice.

The positive checks to population include all the causes which tend in any way prematurely to shorten the duration of human life; such as unwholesome occupations, severe labour and exposure to the seasons, bad and insufficient food and clothing, arising from poverty, bad nursing of children, excesses of all kinds, great towns and manufactories, the whole train of common diseases and epidemics, wars, infanticide, plague, and famine. Of these positive checks, those which appear to arise from the laws of nature may be called exclusively misery; and those which we bring upon ourselves, such as wars, excesses of all kinds, and many others, which it would be in our power to avoid, are of a mixed nature. They are brought upon us by vice, and their consequences are misery.

Some of these checks, in various combinations, and operating with various force, are constantly in action in all the countries with which we are acquainted, and form the immediate causes which keep the population on a level with the means of subsistence.

Mr Malthus, in his work on this subject, has taken a view of the checks of population in most of the countries of which we have the best accounts. His object was evidently to trace in each country those checks which appeared to be most effective in repressing population; and to endeavour to answer the question generally which had been applied particularly to New Holland by Captain Cook, namely, By what means is the population of this country kept down to the number which it can subsist?

Prudential restraint on marriage.

It was hardly to be expected, however, that the general accounts of countries which are to be met with should contain a sufficient number of details of the kind required to enable us to ascertain what portion of the natural increase of population each individual check which could be traced had the power to overcome. In particular, it was not to be expected, that any accounts could inform us of the degree in which moral restraint prevails when taken in its strictest sense. It is necessary, therefore, to attend chiefly to the greater or smaller number of persons who remain unmarried, or marry late; and the delay of marriage, owing to the difficulty of providing for a family, when the degree of irregularity to which it may lead cannot be ascertained, may be usefully called the prudential restraint on marriage and population. And this will be found to be the chief mode in which the preventive check practically operates.

But if the preventive check to population, that check which can alone supersede great misery and mortality, operates chiefly by a prudential restraint on marriage, it will be obvious, as was before stated, that direct legislation cannot do much. Prudence cannot be enforced by laws, without a great violation of natural liberty, and a great risk of producing more evil than good. But still the very great influence of a just and enlightened government, and the perfect security of property in creating habits of prudence, cannot for a moment be questioned. The principal causes and effects of these habits are thus stated in Mr Malthus's last work.[1]

Causes which principally affect the habits of the labouring classes.

"From high wages, or the power of commanding a large portion of the necessaries of life, two very different results may follow; one, that of a rapid increase of population, in which case the high wages are chiefly spent in the maintenance of large and frequent families; and the other, that of a decided improvement in the modes of subsistence, and the conveniences and comforts enjoyed, without a proportionate acceleration in the rate of increase.

"In looking to these different results, the causes of them will evidently appear to be the different habits existing among the people of different countries, and at different times. In an inquiry into the causes of these different habits, we shall generally be able to trace those which produce the first result to all the circumstances which contribute to depress the lower classes of the people, which make them unable or unwilling to reason from the past to the future, and ready to acquiesce, for the sake of present gratification, in a very low standard of comfort and respectability; and those which produce the second result, to all the circumstances which tend to elevate the character of the lower classes of society, which make them approach the nearest to beings who "look before and after," and who, consequently, cannot acquiesce patiently in the thought of depriving themselves and their children of the means of being respectable, virtuous, and happy.

"Among the circumstances which contribute to the character first described, the most efficient will be found to be despotism, oppression, and ignorance; among those which contribute to the latter character, civil and political liberty, and education.

"Of all the causes which tend to encourage prudential habits among the lower classes of society, the most essential is unquestionably civil liberty. No people can be much accustomed to form plans for the future, who do not feel assured that their industrious exertions, while fair and honourable, will be allowed to have free scope; and that the property which they either possess or may acquire will be secured to them by a known code of just laws impartially administered. But it has been found by experience, that civil liberty cannot be permanently secured without political liberty; consequently political liberty becomes almost equally essential, and, in addition to its being necessary in this point of view, its obvious tendency to teach the lower classes of society to respect themselves, by obliging the higher classes to respect them, must contribute greatly to all the good effects of civil liberty."

"With regard to education, it might certainly be made general under a bad form of government, and might be very deficient under one in other respects good; but it must be allowed that the chances, both with regard to its quality and its prevalence, are greatly in favour of the latter. Education alone could do little against insecurity of property; but it would powerfully assist all the favourable consequences to be expected from civil and political liberty, which could not indeed be considered as complete without it."

The varying prevalence of these habits, owing to the causes above referred to, combined with the smaller or greater mortality occasioned by other customs, and the varying effects of soil and climate, must necessarily produce great differences in different countries, and at different periods, in the character of the predominant checks to population, and the force of each. And this inference, which inevitably follows from theory, is fully confirmed by experience.

The positive chec to population predominate in ancien times.

It appears, for instance, from the accounts we have received of ancient nations, and of the less civilized parts of the world, that war and violent diseases were the predominant checks to their population. The frequency of wars, and the dreadful devastations of mankind occasioned by them, united with the plagues, famines, and mortal epidemics of which there are records, must have caused such a consumption of the human species, that the exertion of the utmost power of increase must, in many cases, have been insufficient to supply it; and we see at once the source of those encouragements to marriage, and efforts to increase population, which, with inconsiderable exceptions, distinguished the legislation and general policy of ancient times. Yet there were some few men of more extended views, who, when they were looking to the settlement of a society in a more improved state, were fully aware, that under the most beautiful form of government which their imagination could conceive, the greatest poverty and distress might be felt from a too rapid increase of population. And the remedies which they proposed were strong and violent in proportion to the greatness of the evil which they apprehended. Even the practical legislators who encouraged marriage, seemed to think that the supplies of children might sometimes follow too rapidly for the means of supporting them; and it appears to have been with a view to provide against this difficulty, and of preventing it from discouraging marriage, that they frequently sanctioned the inhuman practice of infanticide.

Under these circumstances, it is not to be supposed that the prudential restraint on marriage should have operated to any considerable extent. Except in a few cases where a general corruption of morals prevailed, which might act as a preventive check of the most vicious kind, a large portion of the procreative power was called into action, the occasional redundancy from which was checked by violent causes. These causes will be found resolvable almost wholly into vice and misery; the first of which, and a large portion of the second, it is always in the power of man to avoid.

Prudent restraint the pred minant check to populati in mode times.

In a review of the checks to population in the different states of modern Europe, it appears that the positive checks to population have prevailed less, and the preventive checks more, than in ancient times, and in the more uncultivated parts of the world. The destruction occasioned by war has unquestionably abated, both on account of its occurring, on the whole, less frequently, and its ravages not being so fatal, either to man or the means of his support, as they were formerly. And although, in the earlier periods of the history of modern Europe, plagues, famines, and mortal epidemics were not unfrequent, yet, as civilization and improvement have advanced, both their frequency and their mortality have been greatly reduced, and in some countries they are now almost unknown. This diminution of the positive checks to population, as it has been certainly much greater in proportion than the actual increase of food and population, must necessarily have been accompanied by an increasing operation of the preventive checks; and probably it may be said with truth, that in almost all the more improved countries of modern Europe, the principal check which at present keeps the population down to the level of the actual means of subsistence, is the prudential restraint on marriage.

Yet in comparing together the accounts and registers of the different countries of modern times, we shall still find a vast difference in the character and force of the checks which are mainly in action; and it is precisely in this point

---

[1] Principles of Political Economy, c. iv. sect. 2.

Difference in the character and force of the checks in different countries.

of view that these accounts afford the most important instruction. Some parts of Europe are yet in an unimproved state, and are still subject to frequent plagues and mortal epidemics. In these countries, as might be expected, few traces are to be found of the prudential restraint on marriage. But even in improved countries, the circumstances may be such as to occasion a great mortality. Large towns are known to be unfavourable to health, particularly to the health of young children; and the unwholesomeness of marshy situations may be such as in some cases to balance the principle of increase, even when nearly the whole of the procreative power is called into action, which is seldom the case in large towns.

Thus, in the registers of twenty-two Dutch villages given by Sussmilch,[1] and quoted by Mr Malthus, the mortality (occasioned, as may be supposed, chiefly by the natural unhealthiness of the country) was as high as one in twenty-two or twenty-three, instead of the more common proportion of one in thirty-five or forty; and the consequence was, that the marriages, instead of being in the usual proportion of one in about 108 of the population, were in the extraordinary high proportion of one in sixty-four;[2] showing a most unusual frequency of marriage, while, on account of the great mortality, the number of inhabitants was nearly stationary, and the births and deaths about equal.

On the other hand, in Norway, where the climate and modes of living seem to be extremely favourable to health, and the mortality was only one in forty-eight, the prudential restraint on marriage was called more than usually into action, and the marriages were only one in 130 of the population.

Gradual diminution in the proportion of marriages.

These may be considered as extreme cases, but the same result in different degrees is observable in the registers of all countries; and it is particularly to be remarked, that in those countries where registers of births, deaths, and marriages have been kept for a considerable time, the progressive diminution or mortality occasioned by the introduction of habits more favourable to health, and the consequent diminution of plagues and mortal epidemics, have been accompanied invariably by a smaller proportion of marriages and births. Sussmilch has given some striking instances of the gradual diminution in the proportion of the number of marriages during a part of the last century.[3]

In the town of Leipsic, in the year 1620, the annual marriages were to the population as 1 to 82; from the year 1741 to 1756, they were as 1 to 120.

In Augsburg, in 1510, the proportion of marriages to the population was 1 in 86; in 1750 as 1 to 123.

In Dantzic, in the year 1705, the proportion was as 1 to 89; in 1745, as 1 to 118.

In the dukedom of Magdeburg, in 1700, the proportion was as 1 to 87; from 1752 to 1755, as 1 to 125.

In the principality of Halberstadt, in 1690, the proportion was as 1 to 88; in 1756, as 1 to 112.

In the dukedom of Cleves, in 1705, the proportion was as 1 to 83; in 1755, as 1 to 100.

In the churmark of Brandenburg, in 1700, the proportion was as 1 to 76; and in 1755, as 1 to 108.

Instances of this kind are numerous, and they tend to show the dependence of the marriages on the deaths in all old countries. A greater mortality almost invariably produces a greater number of marriages; and it must be equally certain, that except where the means of subsistence can be adequately increased, a greater proportion of marriages must occasion a greater mortality.

Dependence of the births and marriages on the deaths.

The proportion of yearly births to the whole population must evidently depend principally on the proportion of marriages; and it appears, consequently, from registers, that in countries which will not admit of any considerable increase of population, the births, as well as the marriages, are mainly influenced by the deaths. When an actual decrease of population is not taking place, the births will always supply the vacancies made by death, and exactly so much more as the increasing wealth of the country and the demand for labour will admit. Everywhere in the intervals of plagues, epidemics, and destructive wars, the births considerably exceed the deaths; but while from these and other causes the mortality in different countries is extremely various, it appears from registers that, with the exception above stated, the births vary in the same proportion.[4]

Thus, in 39 villages of Holland, where the deaths, at the time to which the registers refer, were about 1 in 23, the births were also 1 in 23. In 15 villages round Paris, the births bore the same or even a greater proportion to the whole population, on account of a still greater mortality, the births being 1 in $22\frac{7}{10}$ths, and the deaths the same. In the small towns of Brandenburg, which were in an increasing state, the mortality was 1 in 29, and the births 1 in $24\frac{7}{10}$ths. In Sweden, where the mortality was about 1 in $34\frac{1}{2}$, the births were 1 in 28. In 1056 villages of Brandenburg, in which the mortality was about 1 in 39 or 40, the births were about 1 in 30. In Norway, where the mortality was 1 in 48, the births were 1 in 34.

In all these instances the births are evidently measured by the deaths, after making a proper allowance for the excess of births which the state of each country will admit. In such a country as Russia, this allowance must be great; as, although the mortality might perhaps be taken as low as 1 in 48 or 50, the births were as high as 1 in 26, owing to the increasing resources of the country, which admit of a rapid increase of the population.

Dependence of the births on the deaths illustrated in Switzerland.

Of all the countries which Mr Malthus has reviewed, there is none which so strikingly illustrates the most important fact of the dependence of the proportions of marriages and births on the deaths, and the general principles of population, as Switzerland. It appears, that between 1760 and 1770, an alarm prevailed respecting the continued depopulation of the country; and, to ascertain the point, M. Muret, minister of Vevay, made a very laborious and careful search into the registers of different parishes from the time of their first establishment. He compared the number of births which had taken place during three different periods of seventy years each, the first ending in 1620, the second in 1690, and the third in 1760. And finding by this comparison, that the number of births was less in the second period than in the first, and less in the third period than in the second, he considered the evidence of a continued depopulation of the country from the year 1055 as incontrovertible.[5] But the accounts which he himself produces clearly show, that, in the earlier periods to which he refers, the mortality was very much greater than in the latter; and that the greater *number* of births found in the registers formerly, was not owing to a greater population, but to the greater *proportion* of births which always accompanies a greater mortality.

It appears from accounts which are entirely to be depended on, that during the last period the mortality was extraordinarily small, and the proportion of children reared from infancy to puberty extraordinarily great. At the time when M. Muret wrote his paper, in 1766, the proportion of deaths to the population in the Pays de Vaud was 1 in 45, of births 1 in 36, and of marriages 1 in 140. These are all very small proportions of births, deaths, and marriages, compared with other countries; but the state of things must have been totally different in the sixteenth and seventeenth centuries. M. Muret gives a list of all the plagues which had prevailed in Switzerland from 1520, from which it appears that this dreadful scourge desolated the country at short intervals during the whole of the first period, and extended its occasional ravages to within twenty-two years of the termination of the second. We may safely conclude, that, in these times, the average mortality was very much greater than at present. But what puts the question beyond a doubt, is the great mortality which prevailed in the neighbouring town of Geneva in the sixteenth century, and its gradual diminution in the seventeenth and eighteenth. It appears from calculations, published in the *Bibliothèque Britannique* (tom. iv. p. 328), that in the sixteenth century the probability of life, or the age to which half of the born lived, was only 4·883, or under four years and eleven months; and the mean life, or the average number of years due to each person, 18·511, or about eighteen years and a half. In the seventeenth century, the probability of life in Geneva was 11·607, about eleven years and seven months; the mean life 23·358, or twenty three years and four months. In the eighteenth century, the probability of life had increased to 27·183, twenty-seven years and two months; and the mean life to thirty-two years and two months.

There can be no doubt, from the prevalence of the plague, and its gradual extinction, as noticed by M. Muret, that a diminution of mortality of the same kind, though not perhaps to the same extent, must have taken place in Switzerland; but if, with a mortality which could not have been less than one in thirty or thirty-two, the proportion of births had been what it was when M. Muret wrote, it is quite evident that the country would have been rapidly depopulated. But as it is known, from the actual amount of births found in the registers, that this was not the case, it follows as a necessary consequence, that the greater mortality of former times was accompanied by a greater proportion of births. And this at once shows the error of attempting to determine the actual population, either of different countries, or of different periods in the same country, by the amount of the births; and the strong tendency of population to fill up all vacancies, and very rarely to be limited by any other cause than the difficulty of supporting a family.

Swizerland and the Pays de Vaud afford other most striking instances of the dependence of the births on the deaths; and the accounts of them are perhaps more to be depended upon, as they appear to contradict the preconceived opinions of the person who collected them.

Speaking of the want of fruitfulness in the Swiss women, M. Muret says, that Prussia, Brandenburg, Sweden, France, and indeed every country the registers of which he had seen, give a greater proportion of baptisms to the number of inhabitants than the Pays de Vaud, where this proportion is only as 1 to 36. He adds, that from calculations lately made in the Lyonnois, it appeared that in Lyons itself the proportion of baptisms was 1 in 28, in the small towns 1 in 25, and in the villages 1 in 23 or 24. What a prodigious difference, he exclaims, between the Lyonnois and the Pays de Vaud, where the most favourable proportion, and that only in two small parishes of extraordinary fecundity, is not above 1 in 26, and in many parishes it is considerably less than 1 in 40. The same difference, he remarks, takes place in the mean life. In the Lyonnois it is little above 25 years; while in the Pays de Vaud, the lowest mean life, and that only in a single marshy and unhealthy parish, is $29\frac{1}{2}$ years, and in many places it is above 45 years.

"But whence comes it," he says, "that the country where children escape the best from the dangers of infancy, and where the mean life, in whatever way the calculation is made, is higher than in any other, should be precisely that in which the fecundity is the smallest? How comes it, again, that, of all our parishes, the one which gives the mean life the highest should also be the one where the tendency to increase is the smallest?"[1]

To resolve this question, M. Muret says, "I will hazard a conjecture, which, however, I give only as such. Is it not that, in order to maintain in all places a proper equilibrium of population, God has wisely ordered things in such a manner as that the force of life in each country should be in the inverse ratio of its fecundity? In fact, experience verifies my conjecture. Leyzin, a village in the Alps, with a population of 400 persons, produces but a little above eight children a year. The Pays de Vaud, in general, in proportion to the same number of inhabitants, produces eleven, and the Lyonnois sixteen. But if it happen, that at the age of twenty years, the eight, the eleven, and the sixteen are reduced to the same number, it will appear that the force of life gives in one place what fecundity does in another. And thus the most healthy countries, having less fecundity, will not over-people themselves, and the unhealthy countries, by their extraordinary fecundity, will be able to sustain their population."

These facts and observations are full of the most important instruction, and strikingly illustrate the principle of population. The three gradations in the proportions of births which are here so distinctly presented to our view, may be considered as representing that variety in the proportion of births which is known to take place in different countries and at different periods; and the practical question is, whether, when this variety prevails without a proportionate difference in the rate of increase, which is almost universally the case, we are to suppose, with M. Muret, that a special providence is called into action to render women less prolific in healthy countries, and where improved habits of cleanliness have banished plagues and mortal epidemics; or to suppose, as experience warrants, that the smaller mortality of healthy and improved countries is balanced by the greater prevalence of the prudential restraint on marriage and population.

The subject is seen with particular clearness in Switzerland, on account of the population of some of the districts being stationary. The number of inhabitants on the Alps was supposed to have diminished. This was probably an error; but it is not improbable that they should have remained stationary, or nearly so. There is no land so little capable of providing for an increasing population as mountainous pastures. When they have been once fully stocked with cattle, little more can be done; and if there be neither emigration to take off the superabundant numbers, nor manufactures wherewith to purchase an additional quantity of food, the deaths must equal the births.

This was the case with the Alpine parish of Leyzin before referred to, where, for a period of thirty years, the mortality and the proportion of births almost accurately kept pace with each other; and where, in consequence, if the positive checks to population had been unusually small, the preventive checks must have been unusually great. In the parish of Leyzin, according to M. Muret, the probability of life was as high as sixty-one years;[2] but it is obvious that this extraordinary degree of healthiness could not *possibly* have taken place under the actual circumstances of the parish with respect to the means of subsistence, if it had not been accompanied by a proportionate action of the prudential restraint on marriage; and accordingly the subsisting marriages, being late and unprolific, yielded only one birth to every twelve; the births were only one in forty-nine, and the number of persons below sixteen was only one fourth of the population.

---

[1] *Mémoires, &c. par la Société Economique de Berne*, 1766, pp. 48 *et seq.*

[2] *Ibid.* table v. p. 65 of the tables.

There can be little doubt that in the present case the extreme healthiness of the people, arising from their situation and employments, had more effect in producing the prudential check to population than the prudential check in producing the extreme healthiness; yet it is quite certain that they must constantly act and re-act upon each other, and that if, when the circumstances are such as to furnish no adequate means for the support of an increased population, and no relief in emigration, the prudential check does not prevail, no degree of natural healthiness could prevent an excessive mortality. Yet to occasion such a mortality, a much greater degree of poverty and misery must have taken place than in districts less favourably circumstanced with regard to health; and we see at once the reason why, in countries of mountainous pasture, if there be no vent in emigration, the necessity of the prudential check should be more strongly forced on the attention of the inhabitants, and should in consequence prevail to a greater degree.

Differences in the registers of different countries.

Taking countries in general, there will necessarily be differences as to natural healthiness in all the gradations, from the most marshy habitable situations to the most pure and salubrious air. These differences will be further increased by the nature of the employments of the people, their habits of cleanliness, and their care in preventing the spread of epidemics. If in no country was there any difficulty in obtaining the means of subsistence, these different degrees of healthiness would make a great difference in the progress of population; and as there are many countries naturally more healthy than the United States of America, we should have instances of a more rapid increase than that which has there taken place. But as the actual progress of population is, with very few exceptions, determined by the relative difficulty of procuring the means of subsistence, and not by the relative natural powers of increase, it is found by experience that, except in extreme cases, the actual progress of population is little affected by unhealthiness or healthiness; but that these circumstances show themselves most powerfully in the character of the checks which keep the population down to the level of the means of subsistence, and occasion that sort of variety in the registers of different countries which was noticed in the instances mentioned by M. Muret.

Thus the population of two or three countries may be increasing at nearly the same rate, but one may be increasing chiefly from a great proportion of births, another from a small proportion of deaths, and a third from a more common proportion of both, in which three different cases the structure of the population, and the registers of births, deaths, and marriages, will be essentially different.

The rate at which the population of Sweden and Norway was increasing, at the time referred to by Mr Malthus, was not far from the same; but their registers differed in almost all points. While the births in Sweden were 1 in 28 of the population, the births in Norway were only 1 in 34; while the marriages in Sweden were 1 in 112, in Norway they were only 1 in 130; and while the mortality in Sweden was 1 in $34\frac{1}{2}$, in Norway it was only 1 in 48.[1] These different proportions of births, deaths, and marriages, must essentially alter the whole structure of the population. The proportion of persons living at different ages would be essentially different; the generations in one country would pass away sooner than the generations in the other; and Sweden might be said to increase principally from the large proportion of its births, and Norway from the small proportion of its deaths, or its small mortality.

A large proportion of births, when they have room to expand themselves, is the most powerful element of increase, and is absolutely necessary in order to effect the shortest period of doubling with which we are acquainted; but two countries may have nearly the same proportion of births, and yet the population of one be quite stationary, while the population of the other is increasing with the greatest known rapidity. The proportion of births in the Dutch villages first noticed approaches towards that of the United States of America; yet in the one case the population did not increase at all, and in the other it has increased so fast as to be taken as a specimen of the natural progress of population when interrupted by the fewest checks to which human society is subject. In this case, though the proportions of births and marriages to the whole population might not be very unlike, and possibly no very great difference might appear in the proportion of marriages to births, the other points in the registers would be in the opposite extremes. While the mortality in the Dutch villages was as high as 1 in 22, it would probably be 1 in 41, or less, in the United States. While the births and deaths in the Dutch villages were in the ratio of equality, in the United States they would be nearly in the proportion of 41 to 19.

In the same manner, two countries might have nearly the same mortality, and yet, in other points, be very different; and while one was increasing most rapidly, the other might be increasing very slowly. The proportion of deaths to the population in the Pays de Vaud is not very essentially different from that of the United States, but the proportion of births and the structure of the population present the most striking contrasts. The proportion of births for the whole of the Pays de Vaud was, according to M. Muret, 1 in 36, in many parishes it was considerably less than 1 in 40, and in one parish as low as 1 in 49; while, in the United States, it must be somewhere between 1 in 19 and 1 in 20. The structure of the population was different accordingly. In the whole of the Pays de Vaud, the proportion of the population under sixteen was one third; in many parts, and in the whole of the Canton of Berne, one fourth; while in the United States, it is as high as one half.

Variations in the age to which half of the born live in different countries.

We have seen, that, according to M. Muret, the probability of life, or the age to which half the born live, was, in the extraordinary parish of Leyzin, as high as 61 years. On the same authority, it appears that in nine other parishes of the Alps it was as high as 47; in 41 parishes of the Pays de Vaud and Jura 42; in 12 corn parishes 40; in 18 parishes among the great vineyards 37, in one marshy parish 24.[2] From other authorities we learn, that in country villages and parishes, the age to which half of the born live is such, that the major part will probably live to marry.[3] In the parish of Ackworth, in Yorkshire, it appears from an exact account kept by Dr Lee, of the ages at which all died there for twenty years from 1747 to 1767, that half the inhabitants live to the age of 46 (Price, vol. ii. p. 35, 7th edit.); and if the same account had been kept in many of the other healthy parishes in England, where the yearly mortality, instead of being 1 in 47 as in Ackworth, was 1 in 60, 1 in 66, and even 1 in 75 (vol. ii. p. 224), half of the born would be found to have lived to above 50 or 55. In the whole of Sweden, where the annual mortality, at the time referred to by Dr Price, was greater than 1 in 35, it appears from his tables, that half of the born must have lived to above 33 (vol. ii. p. 413, 7th edit.); and in Great Britain generally, where the mortality at present, after making due allowance for the omissions in the deaths, appears to be less than 1 in 51, it cannot be doubted that there is scarcely a village in the country tolerably well situated, where half of the born do not live till above 40. In towns the case is very different. According to the data collected by Dr Price, one half of the born died in London under three years of age, in Vienna and Stockholm under two, in Manchester under five, in Northampton under ten (vol. ii. p. 33); and although in most of these towns, particularly those in England, a great improvement has taken place in their healthiness of late years, yet still they will always fall far short of the healthiness of country situations.

---

[1] See Malthus on Population, chapters i. and ii. of book ii.

Mémoires, &c. par la Société Economique de Berne, 1766, table viii. p. 92 of the tables. As these calculations seem all to have been made from mortuary registers, they are all too low, except where the population was absolutely stationary.

[3] Graunt's and Short's Observations, &c. referred to by Dr Price, vol. ii. pp. 41, 42, &c. 7th edition.

The age to which half the born live appears, therefore, to vary in different countries and places, and under different circumstances, in the very extraordinary degree of from 3 to 60.[1]

Variations in the expectation of life in different countries.

The mean age of death, or the expectation of life, must necessarily be more steady; yet it appears to vary from about 16 or 17 to 50.

In Stockholm, according to a table calculated by Dr Price, from the medium of three different enumerations in 1757, 1760, and 1763, the expectation of life for males at birth was 14·25, and for females 18·10.[2] Taken together, the expectation of life was a little above 16. In Vienna, as appears from another table, it was 16½.[3] While, according to M. Muret, at Leyzin, the expectation of life at birth was, about the same period, 50 years.[4]

Variations in the annual mortality.

The annual mortality, which is different, both from the age to which half of the born live, and the mean age of death, is found to vary in different places and countries, from about 1 in 19 to about 1 in 70. In Stockholm, the annual mortality was but 1 in 19 (Price's Observations, vol. ii. p. 136); and in some of the villages in England, even at the time that Dr Price wrote, it was as low as 1 in 70 and 1 in 75.

Proportion of births to the population.

The proportion of births to the population appears to vary in different countries and under different circumstances, from about 1 in 17 to 1 in 49. In New Spain, according to Humboldt, it was 1 in 17. In New Jersey, according to the rate of increase determined by the census taken in 1738 and seven years afterwards, the proportion of births must have been about 1 in 18. (Price, vol. ii. p. 50.) At present, as far as can be collected from scattered facts and inferences, the proportion of births in the whole of the United States is about 1 to 19. In the table for Prussia and Lithuania given by Sussmilch, it appears, that after the great plague of 1709 and 1710, and omitting the extraordinary year immediately subsequent, the proportion of births in the five years ending with 1716 was 1 in less than 17;[5] while, according to M. Muret, in the parish of Leyzin, the proportion of births was only 1 in 49 of the population.

Variations in the number of subsisting marriages to one annual birth.

The number of subsisting marriages which yields one annual birth appears to vary from 12 to 4, and the two extreme cases occur in what may be called the same country, and are both noticed by M. Muret; the one in the parish of Leyzin, which presents all the symptoms of the prudential check to population in the greatest excess, and where twelve subsisting marriages yield only one annual birth; and the other in the parish of St Cergue, in the Jura, where marriage is encouraged by the habit of emigration, and four subsisting marriages are sufficient to yield one annual birth.

Different proportions of th populatio under 16.

The proportion of the population under 16 years of age to that above 16 seems to vary in different countries and places, and under different circumstances, from one half to one fourth. In the United States, it appears by the late census that it is one half; while in the canton of Berne it is not much more than one fourth, and in the parish of Leyzin not more than one fourth.[6]

Variation in the mo tality under 15.

The mortality under the age of 15 varies in different places and circumstances, from above two thirds to one fifth. It appears from a table of Dr Price, that in Stockholm above two thirds died under 15 (vol. ii. p. 418); while, according to M. Muret, the proportion of the deaths under the age of 15 was, in the whole of the Pays de Vaud, one third, in many parishes of the Alps one fourth, and in the extraordinary parish of Leyzin only one fifth.[7]

Under these very great variations in the registers of different countries and places, and in the structure of their population, it is obvious that we might fall into the grossest possible errors, by applying the registers of one country to the population of another. Even if we could find a country which was near to a just mean between these opposite extremes, and the registers of which were kept with the greatest accuracy, we could not apply such registers to any other country with a view to any important inferences, unless we knew that the two countries nearly resembled each other, not only in one or two particulars, but in all the main points relating to the structure of their population and the character of the prevailing checks to it.

First tabl of mortality form from the registers towns.

When attention was first directed to tables of mortality with a view to assurances on lives and survivorships, these tables were almost universally formed from the registers of towns, and of the neighbouring villages influenced by them. Buffon, calculating the probability of life from the registers of three parishes in Paris, and twelve country parishes in the neighbourhood, collected by M. Dupré de St Maur, makes it appear that half of the born died under eight years of age. The parishes in Paris seemed to be healthier than the villages in the neighbourhood, which was occasioned by the custom of sending the children from the city to be nursed in the country. Other calculations from the registers of Breslau by Dr Halley, of London by Mr Simpson, and subsequently of Northampton, Warrington, Chester, Norwich, &c. by Dr Price and other writers, all concurred to convey the impression that more than half of the born die under the age of puberty; and though Dr Price, in his two volumes of Observations on Reversionary Payments, takes frequent opportunities of dwelling upon the prodigious difference in the mortality of towns and of country situations, and produces abundance of evidence to show that, taken together, in the actual state of things, half of the born live much beyond the age of puberty; yet, among some persons who have not attended to the subject, the former impression seems still to have remained; and, what is more strange, it has been lately asserted that this must happen from the constitution and course of human nature (Godwin's Answer to Malthus); which is going very much further than to say that it happens under the poverty, distress, and unhealthy occupations which are known to affect the mortality of a considerable body of people in all the nations with which we are acquainted.

---

[1] This last number, stated by M. Muret for the parish of Leyzin, on the Alps, is so very extraordinary, that possibly it may not be correct.

[7] *Ibid.* table xiii. p. 12.

The constitution and course of human nature determinable only by experience.

The constitution and course of human nature can only be determined by experience, and the analogies derived from it; and the kind of experience necessary to determine the point in question is to be obtained only by a reference to registers which inform us of the ages at which the born have died. Now, from the evidence of registers of this kind which have been carefully kept in country parishes, it appears that the age to which half of the born live is much nearer to forty than to the age of puberty. Even in Sweden, where the general mortality is unquestionably very great, owing to the poverty of the labouring classes, and the diseases brought upon them by bad and insufficient food during seasons of scarcity, the age to which half of the born live is, as before stated, above thirty-three;[1] in the whole of the Pays de Vaud it is forty-one; in many particular parishes forty-seven; in a parish in England not so healthy as many others, forty-seven; and as the expectation of life appears, by the late returns from the parish registers of Great Britain, to be as high as in Switzerland, there is little reason to doubt, from the evidence of registers, that the age to which half of the born live in this country can fall but little short of what it is in the Pays de Vaud, that is, it must be somewhere near forty. But it will hardly be contended that there is no premature mortality in Great Britain occasioned by the pressure of poverty, and the effect of large towns and unwholesome occupations. Consequently, unless we are prepared to say that agricultural employments, airy and moderately-sized towns, cleanliness, healthy occupations, and prudence, are against the constitution and course of nature, as applied to reasonable beings, we must acknowledge, that if the constitution and course of nature were carefully observed, and the admonitions which they give properly attended to, half of the born would, in healthy climates, live on an average to forty-five. Taking things, however, as they are, it is obvious that, according to the testimony of the best registers, more than half of the born might live to marry in most countries, even if the average age of marriage was so late as thirty.

Immediate causes of the increase of population.

The immediate cause of the increase of population is the excess of the births above the deaths; and the rate of increase, or the period of doubling, depends upon the proportion which the excess of the births above the deaths bears to the population.

The excess of births is occasioned by, and proportioned to, three causes: 1*st*, the prolificness of the marriages; 2*dly*, the proportion of the born which lives to marry; and, 3*dly*, the earliness of these marriages compared with the expectation of life, or the shortness of a generation by marriage and birth, compared with the passing away of a generation by death.

In order that the full power of increase should be called into action, all these circumstances must be favourable. The marriages must be prolific, owing to their being contracted early; the proportion of the born living to marry must be great, owing both to the tendency to marriage, and the great proportion of births rising to the age of puberty; and the interval between the average age of marriage and the average age of death must be considerable, owing to the great healthiness of the country, and the expectation of life being high. Probably these three causes, each operating with the greatest known force, have never yet been found combined. Even in the United States, though the two first causes operate very powerfully, the expectation of life, and consequently the distance between the age of marriage and the average age of death, is not so favourable as it might be. In general, however, the excess of births which each country can admit being very far short of the full power of increase, the causes above mentioned contribute to the required supply in very various proportions, according to the different circumstances and habits of each state.

Inferences drawn from registers.

It would be very desirable to know something of these proportions, with a view to their influence on the happiness of society. Our main sources of information on this subject are registers of births, deaths, and marriages; but in order to draw just inferences from them, we must consider well what they imply. The following observations and rules, modified from Mr Malthus's chapter on the fruitfulness of marriages, may be useful for this purpose.

Proportion of births to a marriage.

If we suppose a country where the population is stationary, where there are no emigrations, immigrations, or illegitimate children, and where the registers are accurate, then the proportion of the annual births to the annual marriages will accurately express both the number of children born to each marriage, including second and third marriages, and also the proportion of the born which lives to marry once or oftener, while the annual mortality will accurately express the expectation of life.

But if the population be either increasing or decreasing, and the births, deaths, and marriages increasing or decreasing in the same ratio, such a movement will necessarily disturb all the proportions, because the events which are contemporary in the registers are not contemporary in the order of nature.

In the first place, the births of any year cannot, in the order of nature, have come from the contemporary marriages, but must have been derived principally from the marriages of preceding years.

If we were to cut off a period of thirty years in the registers of any country some time ago, and inquire what was the number of births which had been produced by all the marriages included in the period cut off, it is evident, that with the marriages at the beginning of the period will be arranged a number of births proceeding from marriages anterior to it; and at the end a number of births produced by the marriages included in the period will be found arranged with the marriages of a succeeding period. Now, if we could subtract the former number, and add the latter, we should obtain exactly all the births produced by the marriages of the period, and thus ascertain the real prolificness of marriages. If the population had been stationary, the number of births to be added would exactly equal the number to be subtracted, and the proportion of births to marriages, as found in the registers, would exactly represent the real prolificness of marriages. But if the population be increasing, the number to be added would be greater than the number to be subtracted, and of course the proportion of births to marriages, as found in the registers, would always be too small to represent the true prolificness of marriages. A contrary effect would take place in a decreasing population. The question therefore is, what we are to add, and what to subtract, when the births and deaths are not equal.

The average proportion of births to marriages in Europe, as taken from registers, is about four to one. Let us suppose, for the sake of illustration, that each marriage yields four children, one every other year. In this case, wherever the period in the registers is begun, the marriages of the preceding eight years will only have produced half their births, and the other half will be arranged with the marriages within the period, and ought to be subtracted from them. In the same manner the marriages of the last eight years of the period will only have produced half their births, and the other half ought to be added. But half the births of any eight years may be considered as nearly equal to all the births of the succeeding three years and three quarters. In instances of the most rapid increase it will rather exceed the births of the next three years and a half, and in cases of slow increase approach towards the births of the next four years. The mean, therefore, may be taken at three years and three quarters. Consequently, if we subtract the births of the first three years and three quarters, and add the births of the three years and three quarters subsequent to the period, we shall have a number of births nearly equal to the number of births produced by all the marriages included in the period, and, of course, the prolificness of marriages. But if the population of a country be increasing regularly, and the births, deaths, and marriages continue always to bear the same proportion to each other and to the whole population, it is evident that all the births of any period will bear the same proportion to all the births of any other period of the same extent taken a certain number of years later, as the births of any single year to the births of a single year taken the same number of years later. And, consequently, to estimate the prolificness of marriages, we have only to compare the marriages of the present, or any other year, or the mean of five years, with the births of a subsequent year, or the mean of five years taken three years and three quarters later.

---

[1] We allude to the registers and tables referred to by Dr Price. Since his time the health of the country has increased, like that of most of the countries in Europe, and the proportions of both the births and deaths have decidedly diminished.

It has been supposed, in the present instance, that each marriage yields four births; but the proportion of births to marriages apparent in the registers of most of the countries of Europe is four to one, and as the population of most of the countries of Europe is known to be increasing, the prolificness of marriages must be greater than four. If, allowing for this circumstance, we take the distance of four years instead of three years and three quarters, we shall still be sure of not erring in excess. And though undoubtedly the period which we take, whatever it may be, will not answer exactly in different countries, yet its application generally will not be so incorrect as we might at first imagine, because, in countries where the marriages are more prolific, the births generally follow at shorter intervals, and where they are less prolific, at longer intervals; and, with different degrees of prolificness, the length of the period might still remain the same.

Probably, however, the period here assumed, which is the one taken by Mr Malthus, is too short. If, as he says, there is reason to think, that, in almost all registers, the omissions in the births and deaths are greater than in the marriages, there ought to be a greater number of births to each marriage, in which case it would take a longer time to have them in; and if, further, it is probable that a birth every other year is too rapid a succession for those countries where the marriages are frequently late, it may be thought that the births at the distance of five years will more nearly represent the prolificness of marriages than at the distance of four years. But this matter must be left to the judgment of the reader.

At all events, it will follow, from what has been said, that the more rapid is the increase of population, the more will the real prolificness of marriages exceed the proportion of births to marriages in the registers.

The rule which has here been laid down attempts to estimate the prolificness of marriages, taken as they occur; but this prolificness should be carefully distinguished from the prolificness of first marriages, and of married women, and still more from the natural prolificness of women in general, taken at the most favourable age. It is probable that the natural prolificness of women is nearly the same in most parts of the world; but the prolificness of marriages is liable to be affected by a variety of circumstances peculiar to each country, and particularly by the number of second, and third, and late marriages. In all countries the second and third marriages alone form a most important consideration, and materially influence the average proportions. According to Sussmilch, in all Pomerania, from 1748 to 1756 both included, the number of persons who married were 56,956, and of these 10,586 were widows and widowers.[1] According to Busching, in Prussia and Silesia, for the year 1781, out of 29,308 persons who married, 4841 were widows and widowers;[2] and, consequently, the proportion of marriages will be given fully one sixth too much. In estimating the prolificness of married women, the number of illegitimate births would tend, though in a slight degree, to counterbalance the overplus of marriages; and as it is found that the number of widowers who marry again is greater than the number of widows, the whole of the correction should not, on this account, be applied; but in estimating the proportion of the born which lives to marry, which is what we are now about to proceed to, the whole of this correction is always necessary.

Proportio of the bo which liv to marry.

To find the proportion of the born which lives to marry, from registers, we must consider that the marriages of any year can never be contemporary with the births from which they have resulted, but must always be at such a distance from them as is equal to the average age of marriage.

If the population be increasing, the marriages of the present year have resulted from a smaller number of births than the births of the present year; and, of course, the marriages, compared with the contemporary births, will always be too few to represent the proportion of the born which lives to marry, and the contrary will take place if the population be decreasing; and to find this proportion, after having first made the proper correction for second and third marriages, we must compare the marriages of any year with the births of a previous year at the distance of the average age of marriage.[3]

Expecta- tion of li

The third principal object which it is desirable to attain, and of which some estimate may be formed from registers, is the expectation of life. It has before been stated, that, in a country where the births and deaths are equal, the rate of the annual mortality will express the expectation of life, or the average age of death. But if the population be increasing, the actual population of any one year will be greater than would belong to the contemporary deaths, supposing the births equal to the deaths, and less than would belong to the contemporary births, supposing the deaths equal to the births. Consequently, if we divide the actual population by the number of contemporary deaths in an increasing country, the result will be too high to express the average age of death belonging to any given number of births. If we divide the actual population by the number of births, the result will be too low to express this average, or, in other words, to express the expectation of life. And, in order to approximate to the true proportion, we are directed by Dr Price (vol. ii. p. 39, seventh edition), in the absence of better data, to divide the actual population by a mean between the proportions of deaths and births. Consequently, when we know the proportion of births to deaths in any country, and the proportions which they usually bear to the whole population, we may form some estimate of the expectation of life, or the average age of death.

If we attend to these observations in drawing our inferences from registers, we shall generally be able to form an approximating estimate of the prolificness of marriages, the proportion of the born living to marry, and the expectation of life, in different countries and places, and under different circumstances; or if we cannot do this satisfactorily, owing to the varying rate of increase, and the inaccuracy of the registers, we shall at least guard ourselves against drawing incorrect inferences from them in their present state, and reconcile many of the difficulties with which they appear to be accompanied.

---

[1] *Gottliche Ordnung*, vol. i. tables, p. 98.

[2] It is a shorter and more obvious process to compare the marriages at once with the births of the earlier period, than with the deaths, as Mr Malthus has done.

[3] Malthus, vol. ii. p. 140.

rolific- ess of arriages Eng- nd.

Thus, to estimate the prolificness of marriages in England, the proportion of the marriages to the births, according to the parochial returns ending with 1820, was 100 to 369; adding one sixth for the omissions in the births, or on the present occasion only one seventh, in order to make full allowance for illegitimate births, the proportion of marriages to births will be as 100 to 422. These births, at the rate at which the population was increasing in England and Wales from 1810 to 1820, would, in about four years and a half, increase ·07, which, added to 4·22, makes 4·51. Consequently, the prolificness of marriages, taken as they occur, and including second and third marriages, would be 4·51. If we wish to estimate the prolificness of married women, we must subtract from the marriages those which consist of widows who have married again. According to some tables of Sussmilch, this would be little less than one sixth, according to others one eighth. If we take one seventh, and deduct it from the marriages, the proportion will be 1 to 5·26, that is, each married woman will have 5·26 births. But of these married women, some have married at above forty-five years of age, and many more above thirty-five, so that there can be little doubt that, if the births could be collected from all the marriages in which the age of the woman did not exceed thirty-five, nor the age of the man forty-five, the births would appear to be nearly six; and this number would be still further increased if the average age of marriage for males was twenty-two, and for females twenty. These conclusions are fully confirmed by some accurate observations of M. Muret. At Vevay, where the proportion of marriages to births, in the registers, was as ten to thirty-nine, he found that 375 mothers had had 2093 children born alive, by which it appears that each mother had produced 5·55 births. But these, M. Muret observes, were all mothers, which is not the case of all married women. Allowing, however, for the usual proportion of barren wives at Vevay, which was about twenty out of 478, it appears that the married women, one with another, must have had above 5·3 births. Yet this was in a town where he intimates that the inhabitants do not enter into the marriage state at the time when nature calls them, nor, when married, always have as many children as they might have. It is evident, therefore, that the proportions of marriages to births, to be found in registers, require considerable and important corrections, in order to deduce from them just estimates of the prolificness of marriages, the prolificness of married women, and the prolificness of women marrying at the most favourable age. The instance here given is sufficient to illustrate the mode in which the rule should be applied.

roportion f the born ving to arry in ngland.

If we wish to apply the rule for estimating the proportion of the born living to marry in England, we must first take the proportion of marriages to births in the registers. This proportion, as before stated, was, during the ten years ending with 1820, as 100 to 369; which, increased by one sixth, the supposed omissions in the registers of births will be as 100 to 430. But the marriages of the present year must have resulted, not from the births of the present year, but from the births at such an earlier period in the registers as is equal to the average age of marriage. Suppose this age to be twenty-eight, then, at the rate at which the population was increasing, the present marriages must have resulted from a number of births equal to about two thirds of the present number, so as to be to the present marriages in the proportion of 286 instead of 430 to 100. But of the 200 persons forming the 100 marriages, more than one sixth have been married before. Deducting, therefore, one sixth from the marriages, the proportion of the marriages to the births from which they have resulted will be as 100 to 343; or, out of 343 births, 200 have lived to be married once or oftener; from which it would appear, that on account of the late increase in the healthiness of the country, a greater proportion had lived to marry than when Mr Malthus last estimated it; which, together with a slight increase in the prolificness of marriages apparent in the latter registers, may account for the more rapid increase of the population from 1810 to 1820. It should be recollected, however, that as the rate of increase which prevailed from 1810 to 1820 had by no means prevailed during the whole twenty-eight years, the births, from which 200 person had lived to marry in 1820, were decidedly more than 343.

It will be observed how very important the correction for second and third marriages is. Supposing each marriage to yield four births, and the births and deaths to be equal, it might at first be thought necessary, that in order to keep up the population, half of the born should live to marry; but if, on account of the second and third marriages, we subtract one sixth from the marriages, and then compare them with the births, the proportion will be as five to twenty-four; and it will appear, that instead of one half, it will only be necessary, that out of twenty-four births, ten should live to marry. Upon the same principle, if the births were to the marriages as four to one, and exactly half of the born lived to marry, it might be supposed at first that the population would be stationary; but if we subtract one sixth from the marriages, and then compare them with the births, it will be obvious that, on the supposition of half the born living to marry, the births at the earlier period in the registers, at the distance of the age of marriage, must be to the present births as five to six, which would imply a moderate rate of increase.

To estimate the proportion of male births living to marry, we must subtract full one fifth from the marriages; and, according to this correction, if each marriage yielded four births, it would only be necessary that two male children out of five should live to marry, in order to keep up the population. It is necessary, also, in estimating the proportion of male births living to marry, to make allowance for the greater number of males born.

The foregoing illustrations and remarks show the error of supposing that a country must be in a precarious state when the proportion of births to marriages in the registers is less than four to one. If, indeed, this observation were just, the population of many countries in Europe would be in a precarious state, as in many countries the proportion is less than this. But it has been shown in what manner this proportion in the registers should be corrected, in order to make it a just representation of the prolificness of marriages; and if a large part of the born live to marry, and the age of marriage be considerably earlier than the expectation of life, such a proportion in the registers is by no means inconsistent with a rapid increase of population.

In Russia, the proportion of births to marriages is less than four to one; yet, on account of the large proportion of the born living to marry, the early age of marriage, and the high expectation of life, it is one of the countries in Europe which increases the fastest. In England, the population increases much more rapidly than in France; yet in England the proportion of births to marriages in the registers, when allowance has been made for omissions, was, from 1800 to 1810, four to one, while in France it was four and four fifths to one. (Malthus, vol. ii. p. 161. 5th edit.)

In England, indeed, for the ten years from 1810 to 1821, the proportion of births to marriages seems slightly to have exceeded the former proportion, being about 4·22 to 1; but this excess has been accompanied by such a rapidity of increase as would double the population in less than forty-six years; and comparing this rapid rate of increase with the slow increase of France, where the births were to the marriages as four and four fifths to one, and in Sweden, where these proportions were as four and one fourth to one, it follows that the two other causes of the excess of births above the deaths, besides the prolificness of marriages, must have very great power, and that the proportion of births to marriages, as found in registers, when taken alone, is a most uncertain criterion of increase.

Expectation of life in England.

To apply the rule for estimating the average age of death, or the expectation of life, in England, we must first ascertain from the registers the proportions which the births and deaths bear to the whole population. The annual average of the births for the ten years from 1810 to 1821 was 325,506, of the deaths 200,999. Adding one sixth to the births, and one twelfth to the deaths, for the omission in the registers, the births will be 379,757, and the deaths 217,749. The population of England and Wales, according to the census taken in 1810, was 10,502,500, in 1821, 12,218,500,[1] the mean of which is 11,360,500. The average births and deaths, compared with the mean population, give $\frac{1}{29\cdot9}$ as the proportion of the births, and $\frac{1}{52\cdot17}$ as the proportion of the deaths; and, according to Dr Price, the mean between them, which in this case is forty-one, will give the expectation of life. This rule, however, is only a rough approximation, and, in the few cases where sufficient data have been obtained in progressive countries for calculating the expectation of life more accurately, it has turned out to be much nearer to the annual mortality than to the mean here referred to; while, according to the more correct estimates before adverted to, the annual mortality might, with the same expectation of life, be in different countries 1 in 39·38, 1 in 41·97, or 1 in 41·09, according as the population was stationary, or progressive at various rates.

This appears in the table which Dr Price himself calculated for Sweden (vol. ii. p. 410, 7th edit.), founded on data which he considered as quite satisfactory. It also appears in the table for Sweden and Finland, subsequently calculated by Mr Milne from similar data, in his Treatise on Annuities and Assurances, vol. ii. p. 569; and, further, in a table for Sweden and Finland, published in this work, under the head MORTALITY. We have also seen a calculation by Mr Milne, by which it appears that the difference between the annual mortality and the expectation of life goes on increasing with the rate of the increase of the population to a certain point, but afterwards, owing to the increasing proportion of young children included in the population, diminishes; and is less when the population doubles in twenty-five years, than when it doubles in fifty years. Thus, on the three different suppositions of a stationary population, a population doubling in fifty years, and a population doubling in twenty-five years (all subjected to the same law of mortality as that which prevailed in Sweden and Finland during the five years ended with 1805), in the first case, both the expectation of life and the annual mortality would be 39·388, and, of course, the expectation of life would be the same in all the cases; but in the second case, the annual mortality would be 1 in 41·971; and, in the third, 1 in 41·096. It would be difficult, however, or at least premature, without further data, to lay down a general rule, with a view to determine correctly the expectation of life at birth, in countries progressive at various rates. But, from what has been stated, it may safely be concluded, that the expectation of life lies very much nearer the annual mortality, particularly in cases of very rapid increase, than to the mean proposed by Dr Price; and that both the expectation of life, and the age to which half of the born live, are, in most countries, and especially in England, at the present time, considerably higher than they have generally been estimated.

It may be remarked here, in reference to England during the ten years from 1810 to 1821, that the omissions assumed in the births and deaths do not give such proportions as to make the increase of population, from the excess of births above the deaths, answer to the increase determined by the two censuses; an agreement which must necessarily take place if both the enumerations and the registers are accurate, and no external causes disturb the result. An addition of one sixth to the births, and one twelfth to the deaths, seemed to answer correctly for the interval from 1800 to 1810; but to produce the same coincidence under the more rapid increase of the subsequent ten years, either a greater allowance must be made for omissions in the births, or a less allowance for the omissions in the deaths. If we add one fifth instead of one sixth to the births, retaining one twelfth for the deaths, the excess of births above deaths in the ten years will be 1,728,587, the excess according to the censuses being 1,716,000; if we add only one thirtieth to the deaths, retaining one sixth for the births, the excess will be 1,720,502, within 4502 of the excess, as shown by the censuses; whereas, under the actual allowances which have been made for omissions, the excess will be only 1,620,800, leaving a difference of 95,200, and on the wrong side. On account of the almost incredible healthiness, considering our great towns and manufactories, which would be implied by supposing the deaths to be only deficient one thirtieth, an increased omission in the births might be thought more probable; but it is believed, that since 1812 the omissions in the births have been diminished rather than increased; and under this uncertainty it has been thought better to leave the question as it stands at present, rather than attempt to determine it on insufficient data. It should always be remembered, however, that if the increase of population by the enumerations is different from the increase of population by the registers, one or the other must be incorrect.

Expectation of life at birth, and annual mortality, not the same when the population is progressive.

On the supposition that the omissions in the deaths were only one thirtieth, the average mortality, compared with the average population, would be 1 in 54·7; and the proportion of births, with the addition of one sixth, being, as before stated, 1 in 29·9, the expectation of life, according to Dr Price's rule, would be 42·3. On the other supposition, of an omission of one fifth of the births and one twelfth of the deaths, the births would be 1 in 29, and the deaths 1 in 52·17, and the expectation of life would be 40·58.

It appears, then, that when the population of a country is progressive, it would be erroneous to estimate its healthiness by the proportion which the annual mortality bears to the whole population. Healthiness must be measured by the expectation of life; and if, with the same expectation of life, the annual mortality is affected by the rate of increase, it is obvious that the healthiness of different countries may be different, with the same rate of annual mortality.

Mortuary registers fallacious.

But whilst it is evidently necessary that we should be cautious in inferring that a country is healthy just in proportion to the smallness of its annual mortality, we should be still more cautious in inferring that it is unhealthy at all the ages under puberty, on account of the number which appear to die in mortuary registers under that age. Here, as in the preceding case, but in a much greater degree, the excess of the births above the deaths has a powerful effect, but exactly in the opposite direction. When we compare the annual mortality of an increasing country with its actual population, we compare with it a number of deaths which may be said, properly speaking, to belong to an earlier and smaller number of births, and must necessarily represent the country as more healthy than it really is. On the other hand, when, in a mortuary register, we compare the deaths under puberty with those above, if the population be increasing, we evidently compare the deaths belonging to a much greater number of births than those which have furnished the deaths above the age of puberty; and, consequently, these proportions must represent the country as much less healthy than it really is.[1] According to the mortuary registers of Sweden for twenty-one years from 1755 to 1776, more than half of the deaths were under fifteen, but it was by no means true that half of the born died under fifteen.[2] In the tables of mortality for Sweden during the same period, constructed by Dr Price, it appears that half of the born lived to above thirty-three years.[3]

---

[1] Preliminary Observations to Population Abstracts, p. 32.

In the same manner, in drawing inferences from an abstract of the mortuary registers of the principal cities in America, Baltimore, Boston, New York, and Philadelphia, given by Dr Seybert,[4] we must take care not to conclude that the proportions of the deaths which take place under twenty years of age represent the proportions of any given number of births in these cities which die under twenty. As, on account of the excess of the births above the deaths, all the early ages of the population are more numerous in proportion than the other, there will necessarily be a greater proportion of the deaths at these ages than would naturally belong to a given number of births, if each infant born were traced to the age of its death.

In the present case, the abstract is only for a year, and no safe conclusions therefore can be drawn from it; but, so far as it goes, as even, notwithstanding the increase of population, these mortuary registers show that considerably less than half of the deaths take place under twenty (on an average only about 45½ per cent.), it would appear, that in the early ages of life, even the towns of America are more healthy than the whole of Sweden from 1755 to 1776. It should, however, be considered, that though the towns in America may be increasing fast by procreation, they are increasing still faster by the influx of inhabitants from the country; and as these inhabitants generally come to the towns after the age of sixteen, this accession diminishes the proportion of persons in the earlier ages of life so much, that there is probably a larger proportion of mortality at these ages in the country than in the towns.

riterion 'the pre- alence of rudential straint.

One of the most interesting and useful points of view in which registers can be considered, is in the proofs which they afford of the varying prevalence of the prudential check to marriage and population in different countries and places. It has been not an uncommon opinion, and has even been strongly expressed of late years, although the subject has been much better understood than formerly, that the labouring classes of people, under the circumstances in which they are placed, cannot reasonably be expected to attend to prudential considerations in entering upon the marriage state. But that this opinion does them great injustice, is not only obvious to common observation, by which we can scarcely fail to see that numbers delay marriage beyond the period when the passions most strongly prompt to it, but is proved by the registers of different countries, which clearly show, either that a considerable number of persons of a marriageable age never marry, or that they marry comparatively late, and that their marriages are consequently less prolific than if they had married earlier. As the prudential restraint on marriage may show itself in either of these ways, it may prevail nearly in the same degree with a different proportion of the whole population. But on the supposition of the same natural prolificness in the women of most countries, the smallness of the proportion of births will generally indicate, with tolerable correctness, the degree in which the prudential check to population prevails, whether arising principally from late, and consequently unprolific marriages, or from a large proportion of the population dying unmarried.

Referring, then, to the different proportions of births in different countries as the best criterion of the different degrees in which the prudential restraint on marriage operates, it will be recollected that these proportions vary from about one in thirty-six to about one in nineteen or even seventeen, in different countries, and in a much greater degree in different parishes or districts.

A particular parish in the Alps has already been mentioned, where the births were only a forty-ninth part of the population; and it appears by the late returns of the parish registers of England and Wales, that the births in the county of Monmouth are only one in forty-seven, and in Brecon one in fifty-three;[5] which, after making ample allowance for omissions, would show the prevalence of the prudential restraint on marriage in a high degree.

Effect of the absence of prudential restraint.

If in any country all were to marry at twenty or twenty-one, the proportion of the births would probably be more than one in nineteen; and this result would be still more certain if the resources of the country could not support an accelerated rate of increase, than if the means of subsistence were in the greatest abundance, and the demand for labour as effectual as it has ever been in the United States. Of the latter supposition, taking the births at one nineteenth, and the expectation of life the same as it is in England, the effect would be to occasion a most rapid increase of population; and the period of doubling, instead of being about forty-six or forty-eight years, would be less than in America. On the other hand, if the resources of the country could not support a more rapid increase than that which has taken place in England and Wales during the ten years previous to the census of 1821, the effect would be a great diminution in the expectation of life. If the births were one in nineteen instead of one in nearly thirty, the same rate of increase would take place as at present if the annual mortality were increased to about one in twenty-six and a half; and in that case the expectation of life would be reduced in the proportion of from forty-one, or, as is more probable, from above forty-five, to less than twenty-six.[6] This is the kind of effect which must inevitably follow the absence of the prudential check to marriage and population; and it cannot be doubted, that a considerable part of the premature mortality which is found to take place in all parts of the world is occasioned by it. The laws of nature, in application to man as a reasonable being, show no tendency to destroy half of the human race under the age of puberty. This is only done in very particular situations, or when the constant admonitions which these laws give to mankind are obstinately neglected.

---

[1] In the first case, the effect is, in a considerable degree, counteracted by the large proportion of children under four years old, which a rapid increase occasions. In the second case, the effect has no such drawback.

[2] Price's Observations, vol. ii. p. 405, 7th edit.

[3] *Ibid.* table xlv. vol. ii. p. 413.

[4] Statistical Annals, p. 48.

[5] Preliminary Observations, p. 27.

[6] If, as it has appeared, the expectation of life, though by no means the same, does not differ very much from the annual mortality, and the annual mortality in this country during the ten years from 1810 to 1820, after every abatement, appears to be not more than one in fifty-one, the expectation of life cannot be less than forty-five, and is probably greater.

Objection to the principle of population arising from the mortality it must occasion.

It has been said that a tendency in mankind to increase at such a rate as would double the population in twenty-five years, and, if it had full scope, would fill the habitable globe with people in a comparatively short period, cannot be the law of nature, as the very different rate of increase which is actually found to take place must imply such an excessive degree of mortality and destruction of life as to be quite irreconcileable with actual facts and appearances. But the peculiar advantage of a law of increase in a geometrical progression is, that though its power be absolutely immense if it be left unchecked, yet, when this becomes impossible, it may be restrained by a comparatively moderate force. It can never of course happen that any considerable part of that prodigious increase which might be produced by an uninterrupted geometrical progression, should exist, and then be destroyed. The laws of nature, which make food necessary to the life of man, as well as of plants and animals, prevent the continued existence of an excess which cannot be supported, and thus either discourage the production of such an excess, or destroy it in the bud, in such a way as to make it scarcely perceptible to a careless observer. It has been seen, that in some countries of Europe where the actual progress of the population is slower than in many others, as in Switzerland and Norway, for instance, the mortality is considerably less. Here, then, the necessity of a greater check to the natural progress of population produces no increase of mortality. And it appears farther, that even the degree of mortality which in each year would be sufficient to destroy that excess of births which would naturally be produced if all married young, and all could be supported, might take place, and often does take place in particular situations, and yet is very little noticed. About the middle of last century, the mortality in Stockholm and London was about one in nineteen and one in twenty. This is a degree of mortality which would probably keep the births on a level with the deaths, even though all married at twenty. And yet numbers resorted both to Stockholm and London from choice, the greater part probably not aware that, by so doing, they would shorten their own lives and those of their children; and the rest thinking that the difference was not worth attending to, or was at least balanced by the advantages of society and employment which the town presented. There is nothing, therefore, in the actual state of the mortality observed to take place in different countries and situations, which, in the slightest degree, contradicts the supposition of a natural tendency to increase quite as great as that which has been stated.

Objection that mere tendencies are not to be considered.

It has been further remarked, that as, in point of fact, it very rarely happens that mankind continue to increase in a geometrical progression of any kind, and only in a single instance in such a one as to double the population in twenty-five years, it is useless and absurd to lay any stress upon tendencies which never for any length of time together produce their natural effects. But it might really as well be said, that we are not to estimate the natural rate of increase in wheat or sheep, as it is quite certain that their natural tendency to increase has never practically continued to develope itself for so long a time together as that of mankind. Both as a physical and even economical question, it is curious and desirable to know the natural law of increase which prevails among the most important plants and animals. In the same view, it must be still more interesting to know the natural law of increase with respect to man. It may be said, indeed, with truth, that the actual appearances all around us,—the varying rate of increase in different countries, its very slow progress or stationary state in some, and its very rapid progress in others,—must be a mass of anomalies, and quite contrary to the analogies of all the rest of animated nature; if the natural tendency of mankind to increase be not at the least as great as that which is developed under the most favourable circumstances, while in all others it is kept down by the varying difficulties which the state of the soil and other obstacles oppose to it. But the question, as it applies to man, assumes at once a tenfold importance, in reference to the moral and political effects which must result from those checks to increase, the existence and operation of which, in some form or other, no human exertions can by possibility prevent. A field is here opened for the most interesting inquiries which can engage the friends of human happiness.

But, as a preliminary to these inquiries, it is obvious that we must know the degree of force to be overcome, and the varying character of the checks which, in the different countries of the world, are practically found to overcome it; and, for this purpose, the first step must be an endeavour to ascertain the natural law of population, or the rate at which mankind would increase under the fewest known obstacles. Nor can this tendency to increase ever safely be lost sight of in the subsequent inquiries, which have for their object the improvement of the moral condition of man in society.

Right of the poor to full support considered.

The existence of a tendency in mankind to increase, if unchecked, beyond the possibility of an adequate supply of food in a limited territory, must at once determine the question as to the natural right of the poor to full support in a state of society where the law of property is recognised. The question, therefore, resolves itself chiefly into a question relating to the necessity of those laws which establish and protect private property. It has been usual to consider the right of the strongest as the law of nature among mankind as well as among brutes; yet, in so doing, we at once give up the peculiar and distinctive superiority of man as a reasonable being, and class him with the beasts of the field. In the same language, it may be said that the cultivation of the earth is not natural to man. It certainly is not to man, considered merely as an animal without reason. But to a reasonable being, able to look forward to consequences, the laws of nature dictate the cultivation of the earth, both as the means of affording better support to the individual, and of increasing the supplies required for increasing numbers; the dictates of those laws of nature being thus evidently calculated to promote the general good, and increase the mass of human happiness. It is precisely in the same way, and in order to attain the same object, that the laws of nature dictate to man the establishment of property and the absolute necessity of some power in the society capable of protecting it. So strongly have the laws of nature spoken this language to mankind, and so fully has the force of it been felt, that nothing seems to be thought so absolutely intolerable to reasonable beings as the prevalence in the same society of the right of the strongest; and the history of all ages shows, that if men see no other way of putting an end to it, than by establishing arbitrary power in an individual, there is scarcely any degree of tyranny, oppression, and cruelty, which they will not submit to from some single person and his satellites, rather than be at the mercy of the first stronger man who may wish to possess himself of the fruit of their labour. The consequence of this universal and deeply-seated feeling, inevitably produced by the laws of nature, as applied to reasonable beings, is, that the almost certain consequence of anarchy is despotism.

Allowing, then, distinctly, that the right of property is the creature of positive law, yet this law is so early and so imperiously forced on the attention of mankind, that if it cannot be called a natural law, it must be considered as the most natural as well as the most necessary of all positive laws; and the foundation of this pre-eminence is its obvious tendency to promote the general good, and the obvious tendency of the absence of it to degrade mankind to the rank of brutes.

As property is the result of positive law, and the ground on which the law which establishes it rests is the promotion of the public good and the increase of human happiness, it follows, that it may be modified by the same authority by which it was enacted, with a view to the more complete attainment of the objects which it has in view. It may be said, indeed, that every tax for the use of the government, and every country or parish rate, is a modification of this kind. But there is no modification of the law of property having still for its object the increase of human happiness, which must not be defeated by the concession of a right of full support to all that might be born. It may be safely said, therefore, that the concession of such a right, and a right of property, are absolutely incompatible, and cannot exist together.

To what extent assistance may be given even by law to the poorer classes of society when in distress, without defeating the great object of the law of property, is essentially a different question. It depends mainly upon the feelings and habits of the labouring classes of society, and can only be determined by experience. If it be generally considered as so discreditable to receive parochial relief, that great exertions are made to avoid it, and few or none marry with a certain prospect of being obliged to have recourse to it, there is no doubt that those who were really in distress might be adequately assisted, with little danger of a constantly increasing proportion of paupers; and in that case a great good would be attained, without any proportionate evil to counterbalance it. But if, from the numbers of the dependent poor, the discredit of receiving relief is so diminished as to be practically disregarded, so that many marry with the almost certain prospect of becoming paupers, and the proportion of their numbers to the whole population is in consequence continually increasing, it is certain that the partial good attained must be much more than counterbalanced by the general deterioration in the condition of the great mass of the society, and the prospect of its daily growing worse; so that, though, from the inadequate relief which is in many cases granted, the manner in which it is conceded, and other counteracting causes, the operation of poor-laws such as they exist in England might be very different from the effects of a full concession of the right, and a complete fulfilment of the duties resulting from it, yet such a state of things ought to give the most serious alarm to every friend to the happiness of society, and every effort consistent with justice and humanity ought to be made to remedy it. But whatever steps may be taken on this subject, it will be allowed, that with any prospect of legislating for the poor with success, it is necessary to be fully aware of the natural tendency of the labouring classes of society to increase beyond the demand for their labour, or the means of their adequate support, and of the effect of this tendency to throw the greatest difficulties in the way of permanently improving their condition.

It would lead far beyond the limits which must be prescribed to this article, to notice all the various objections which have been made by different writers to the principles which have been here explained. Those which contain in them the slightest degree of plausibility have been answered by Mr Malthus in various parts of the late editions of his work, and particularly in the appendix to the fifth edition, to which we refer the reader. We will only, therefore, further notice the objection which has been made by some persons on religious grounds; for, as it is certainly of great importance that the answer which has been given to it should be kept in mind, we cannot refuse a place to a condensed statement of it at the end of this article.

Religious objection considered.

It has been thought that a tendency in mankind to increase beyond the greatest possible increase of food which could be produced in a limited space, impeaches the goodness of the Deity, and is inconsistent with the letter and spirit of the Scriptures. If this objection were well founded, it would certainly be the most serious one which has been brought forward; but the answer to it appears to be quite satisfactory, and it may be compressed into a very small compass.

First, It appears that the evils arising from the principle of population are exactly of the same kind as the evils arising from the excessive or irregular gratification of the human passions in general, and may equally be avoided by moral restraint. Consequently, there can be no more reason to conclude, from the existence of these evils, that the principle of increase is too strong, than to conclude, from the existence of the vices arising from the human passions, that these passions are all too strong, and require diminution or extinction, instead of regulation and direction.

Secondly, It is almost universally acknowledged, that both the letter and spirit of revelation represent this world as a state of moral discipline and probation. But a state of moral discipline and probation cannot be a state of unmixed happiness, as it necessarily implies difficulties to be overcome, and temptations to be resisted. Now, in the whole range of the laws of nature, not one can be pointed out which so especially accords with this scriptural view of the state of man on earth; as it gives rise to a greater variety of situations and exertions than any other, and marks, in a more general and stronger manner, and nationally as well as individually, the different effects of virtue and vice, of the proper government of the passions, and the culpable indulgence of them. It follows, then, that the principle of population, instead of being inconsistent with Revelation, must be considered as affording strong additional proofs of its truth.

Lastly, It will be acknowledged, that in a state of probation, those laws seem best to accord with the views of a benevolent Creator, which, while they furnish the difficulties and temptations which form the essence of such a state, are of such a nature as to reward those who overcome them with happiness in this life as well as in the next. But the law of population answers particularly to this description. Each individual has the power of avoiding the evil consequences to himself and society resulting from it, by the practice of a virtue dictated to him by the light of nature, and sanctioned by revealed religion. And as there can be no question that this virtue tends greatly to improve the condition and increase the comforts both of the individuals who practise it, and through them of the whole society, the ways of God to man with regard to this great law are completely vindicated.

Subjoined are two tables, which may assist the reader in calculating the rate of increase in different countries, under different circumstances, and from different data. The first is the table calculated by Euler, and printed in Mr Malthus's work, at the end of his chapter on the Fruitfulness of Marriage; and the second has been calculated by Mr Bridge of Cambridge, well known as an able mathematician, and most useful elementary writer.

The first is to be used when it is wished to estimate the rate of increase by the proportions of the births to the deaths, and of these to the whole population. The yearly increase of people, independently of immigration, is the yearly excess of the births above the deaths; and the yearly rate of increase is measured by the proportion which this excess bears to the whole population. The fraction expressing the deaths must therefore be subtracted from the fraction expressing the births, and the remainder will be the fraction expressing the yearly rate of increase; opposite to which will be found the number of years in which the population will double itself, supposing the yearly rate of increase to continue the same for a sufficient length of time.

The second table is to be used when it is wished to know the period of doubling, resulting from a given per centage increase in ten years, determined by enumeration. An estimate of population from births and deaths is always liable to much uncertainty, on account of the varying proportions which they bear to the population. The only remedy for this uncertainty is a census; and as the useful custom of taking a census of the population every ten years has latterly prevailed in some countries, the second table is constructed to show the period of doubling, or general rate of increase, which results from any given per centage increase in ten years. The first column represents the per centage increase in ten years determined by two enumerations; and the second column the number of years in which the population will double itself, supposing it to proceed at the same rate. (Y. Y. Y. Y.)

* Not slaves, but " indented coloured servants."

PORCELAIN.

Porcelain.

Porcelain, in its more general signification, comprehends all kinds of earthen ware, which are white, semitransparent, and have some degree of a vitreous texture. Hence, in this extensive meaning of the term, it includes all kinds of pottery, stoneware, delft ware, &c. But in a more limited sense, the word *Porcelain* is employed to denote only the finer kinds of earthen ware; and because this kind of ware has been, from time immemorial, manufactured in the greatest degree of perfection in China, it has obtained the name of *Chinese Porcelain*, or *China Ware*.

Derivation of the name.

In the Chinese language, porcelain is denoted by the word *tse-ki*, so that the derivation of the term is not to be sought for in that language; and hence it is supposed to be of European extraction, and to be derived from the Portuguese, in which language the word *porcellano* signifies a cup or vessel.

Porcelain first brought from Japan and China.

The first porcelain which was seen in Europe was brought from Japan and China. Its whiteness, transparency, and fineness of texture, with its elegance and beautiful colours, soon introduced it as an ornament of the tables of the rich and powerful, whilst, at the same time, it excited the admiration and industry of the European manufacturer. Attempts were accordingly made to imitate this kind of ware, in different countries of Europe. The first European porcelains were made in Saxony. The manufacture was afterwards introduced into France, and successively into England, Germany, and Italy, where it has arrived at various degrees of perfection, according to the nature of the materials which can be obtained, and the industry and ingenuity of the artist who superintends and directs it. But after all, to whatever degree of perfection the manufacture of this ware has attained in Europe, it must still yield, in excellence and perfection, to the porcelain of eastern countries.

Antiquity of the Chinese manufacture.

Of the antiquity of the manufacture of porcelain in China, little precise information can be expected from a people who have always shown themselves so extremely averse to the freedom of intercourse with other nations. But it is said that the village or town of King-te-ching has furnished the emperors of China with porcelain since the year 442 of the Christian era; and that it is an object of so much attention to the Chinese government, that the manufacture is carried on under the superintendence of one or two mandarins sent from court.

1. *History of the Manufacture of Porcelain in China.*

The fullest account which has as yet been received in Europe of the manufacture of Chinese porcelain, has been given by Father D'Entrecolles, a Catholic missionary, who lived for some time in the village or town where the principal manufactory was established. The account which has been given by the Jesuit of this village, and of the manufacture of porcelain, is extremely interesting.

This village or town, which is celebrated as producing the best porcelain of China, is in the province of Kiang-si, and is said to be a league and a half in length, containing not less than 1,000,000 of inhabitants. Other manufactories, indeed, have been established in different parts of the Chinese empire, and particularly in those places which are convenient for the European trade, as in the provinces of Fo-kien and Canton; but the porcelain produced at these is said to be held in inferior estimation. A Chinese emperor wishing to have a manufacture of porcelain under his own inspection at Pekin, ordered workmen to be collected for the purpose, with all the necessary materials and implements; but after erecting furnaces and other expensive operations, the attempt failed, so that, in the time of D'Entrecolles, King-te-tching continued to be the most celebrated place in China for beautiful porcelain; and from this it was transported to all parts of the world.

Materials employed in its composition.

The chief ingredients which enter into the composition of fine porcelain are petuntse and kaolin, two kinds of earth from the mixture of which the paste is obtained. The petuntse is of a pure white, and, when fully prepared, is in the form of an impalpable powder, so that it is very fine to the touch. The kaolin, he observes, is intermixed with small shining particles. These materials are carried to the manufactory in the shape of bricks. The petuntse originally consists of the fragments of rock dug out from certain quarries, and reduced to powder; and the colour of the stone which answers the purpose best, according to the Chinese, inclines somewhat to green. The fragments of rock are broken to pieces with a large iron club; they are then put into mortars, and by means of levers headed with hard stone, strongly secured with iron, they are reduced to the state of fine powder. The levers, it is scarcely necessary to observe, are moved either by the labour of men, or by water. The powder, which is afterwards collected, is then thrown into a large vessel full of water, which is strongly agitated with an iron shovel. When this mixture has been allowed to settle for some time, a substance resembling cream rises to the top, which is skimmed off, and poured into another vessel also filled with water. The water in the first vessel is again agitated, and the frothy substance which rises to the surface is collected as before, and the same operation is repeated till it appear that nothing remains but a coarse sediment which falls to the bottom by its own weight. This sediment is then carefully collected, and again subjected to the process of pulverization.

The fluid in the second vessel is allowed to remain at rest till a sediment is produced, forming a kind of crust at the bottom; and when the water above seems to be quite transparent, it is poured off by gently inclining the vessel, that the sediment may not be disturbed. The paste is then put into large moulds, and allowed to dry slowly; but before it becomes quite hard, it is divided into small square cakes, which are sold by the hundred. This is the substance which is called by the Chinese *petuntse*, and the name is said to be derived from the colour and form of this paste.

The kaolin, the other substance which is employed in the fabrication of porcelain, requires fewer operations in its preparation than the former, as it is found in nature in a state almost ready for the manufacturer. Of this substance it is said, that there are extensive mines in certain mountains, the external strata of which are composed of a kind of red earth. The kaolin is found in these mines in small lumps, and it is formed into bricks by being subjected to a similar process with the petuntse.

Nature of the finer porcelain.

The fine porcelain, it has been observed, derives its fabric and texture from the kaolin. It is to this that the qualities which it possesses of resisting the most powerful heat is owing; whilst its strength and consistency is obtained by fusion with the petuntse, which enables it to resist the action of the more powerful agents. D'Entrecolles relates an anecdote which he received from a rich Chinese merchant, that the English and Dutch having purchased a quantity of petuntse, conveyed it to Europe for the purpose of manufacturing porcelain; but having procured none of the kaolin, the attempt failed. They wanted, added the Chinese with a smile, to form a body, the flesh of which would support itself without bones.

Substitute for kaolin.

It is said that the Chinese have latterly discovered a new substance which may be employed in the composition of porcelain. This stone is called *hoa-chè*, the first part of the word signifying glutinous, because it is of a saponaceous quality. Porcelain made with this substance is very rare, and bears a much higher price than any other. The grain is extremely fine, and the painting with which it is ornamented, when compared with that of common porcelain, appears to exceed it as much as vellum surpasses paper. This variety of porcelain, it is added, is also remarkable for its lightness. It is besides much more brittle, and it is found very difficult to hit upon the proper degree of heat for tempering it. This substance, we are farther informed, is but rarely employed in the fabrication of the body of the porcelain; the reason of which perhaps is, the scarcity and high price of this precious article, in consequence of which the workman is contented with making it into a fine size, into which the vessel is immersed when it is dry, that it may receive a coat before it is painted and glazed; and by this process he finds that he can commmunicate to the ware a very high degree of beauty. The previous processes employed in the preparation of this substance are similar to those which are followed in the preparation of kaolin. When hoa-chè is extracted from the mine, it is washed in rain or river water, for the purpose of separating a yellowish earth with which it is contaminated. It is then reduced to powder, thrown into a vessel filled with water, and then formed into cakes. The hoa-chè prepared in this manner, without the addition of any other earth, is said to be alone sufficient in the fabrication of porcelain. It is employed, as has already been noticed, as a substitute for kaolin; but, on account of its scarcity, it is much dearer. The price of the former is three times that of the latter, and from this circumstance the value of porcelain made with hoa-chè is much higher than that which is manufactured with kaolin.

Material for glazing porcelain.

The principal ingredients in the fabrication of porcelain are petuntse and kaolin; but to these must be added the glaze or varnish, or, as it is called in the account given of Chinese porcelain, the oil, on which depend its splendour and whiteness. This varnish is of a whitish colour, and is obtained from the same kind of stone which yields the petuntse; but for this purpose the whitest stone is always preferred. The glaze is obtained by a process similar to that which is followed in the preparation of petuntse. The stone is first washed and reduced to powder; it is then thrown into a vessel filled with water, and after being purified, a frothy matter rises to the surface. To 100 pounds of this matter, one pound of a substance called che-kao, is added. This latter is a saline substance, somewhat like alum, which is put into the fire, and allowed to remain till it become red hot, when it is reduced to powder. By the addition of this substance the glaze acquires a greater degree of consistence; but at the same time a proper degree of fluidity must be preserved. The glaze prepared in this manner is not employed alone. Another glaze is mixed with it, which is obtained from lime and ashes; to 100 pounds weight of which is also added one pound of che-kao, or the aluminous substance mentioned above. When the two substances are mixed, it is necessary to attend that they be nearly of the same consistence, and the workman ascertains this point by dipping into each of them some cakes of petuntse; and by a close examination of their surfaces after they are drawn out, he is able to judge of the consistence of the fluids. The proportions of the two which are usually employed, are ten parts of the glaze obtained from the stone, to one of that which is prepared from the lime and from ashes.

Proporti and mixture of th ingredien

In the manufacture of the Chinese porcelain, the first process, after the separate preparation of the materials, is a second purification of the petuntse and kaolin; and when these are found to be in a state of sufficient purity, the workmen proceed to mix the two ingredients together. The proportions employed for the finer kinds of porcelain are equal parts of kaolin and petuntse; for an inferior kind, four parts of kaolin to six of petuntse are employed; and in some kinds of porcelain, only one part of the former is added to three of the latter. This is the smallest proportion of kaolin which is employed in the Chinese manufactories. When the proportions are fixed, and the mixture finished, the mass is thrown into a large pit, which is well paved and cemented. It is then trodden upon, and kneaded till it become hard. This is the most fatiguing part of the labour, for it must be continued without intermission. From the mass prepared in this manner the workmen detach different pieces, which they spread out upon large slates, where they knead and roll them in all directions, taking care that no vacuum be left, and that there be no intermixture of any foreign body. The whole work would be entirely spoiled by the addition of a hair, or a particle of sand. When the paste has been properly prepared, the porcelain, when exposed to heat in the furnace, retains its form without becoming soft, or entering into fusion, and becomes semitransparent, without exhibiting cracks or superficial fissures; but when there is any defect in the mixture or preparation, the porcelain cracks, and becomes warped, or melts in the furnace.

Methods of forming porcelain ware.

The paste being thus prepared, the next operation is to form the vessels for which it is designed. All kinds of plain ware are formed with the wheel. When a cup, for instance, has undergone this operation, the outside of the bottom is quite round. The workman first gives it the requisite height and diameter, and it comes from his hands almost the moment he has received it. Great dexterity and expedition are absolutely necessary, on account of the low price of labour in these manufactories. A workman, it is said, scarcely receives a farthing per board, each board containing no less than twenty-six pieces. The cup then passes to a second workman, by whom the base is formed; after which it is delivered to a third, who applies it to the mould, and gives it the proper form. When it is taken off the mould, it must be carefully turned, and not pressed more to one side than the other; for without this necessary precaution it would become warped or disfigured. The business of the fourth workman is to polish it with the chisel, especially round the edges, and diminish the thickness, in order to give it the proper degree of transparency. Having at length passed through the different hands from whom it receives its form and various ornaments, it then comes to the last workman, who forms the bottom with a chisel. It is wonderful, we are told, to see with how much dexterity and expedition the workmen convey the vessels from one to another; and it is added, that a single piece of porcelain, before it is completely finished, must pass through the hands of no fewer than seventy different workmen. It is indeed, we may observe, to this minute division of labour that its low price is owing; and on the same circumstance depend the remarkable dexterity and expedition which have already been noticed.

Of large works.

In the execution of large works of porcelain, different parts are first formed individually; and when all the pieces are finished, and nearly dry, they are put together and cemented with a paste formed of the same substance, and softened with water. Some time afterwards the seams are polished with a knife on both sides of the vessel, so that when it is covered with a varnish, or glazed, they are so completely concealed, that the least trace of them is not perceptible. It is in this way that spouts, handles, rings, and other parts of a similar nature, are united. And in this way, particularly are fabricated those pieces which are formed upon moulds, or by the hand, such as embossed works, grotesque images, idols, figures of trees or animals, and busts. All these are formed of four or five pieces joined together, which are afterwards brought to perfection by means of instruments proper for carving, polishing, and finishing the different traces which the mould has left imperfect. Flowers and ornaments which are not in relief, are either engraved, or the impression is made by means of a stamp; but ornaments in relief are prepared separately, and added to the pieces of porcelain to which they are destined.

ainting.

The piece of porcelain being prepared according to the operations now described, is next conveyed to the painter; and in this art it is to be observed that the Chinese workmen follow no certain rule, and seem to be unacquainted with any of the principles of perspective. Their knowledge is the effect of practice, guided often by a whimsical imagination. The labour of painting porcelain in the Chinese manufactories is also divided amongst a great number of hands. The business of one man, for instance, is solely limited to the tracing out the first coloured circle with which the brim of the vessel is adorned; another designs the flowers, and a third paints them. One delineates waters and mountains, whilst it is the province of another to draw and paint birds and other animals. Of the painting on Chinese porcelain, it has been observed, that the human figure is often most indifferently executed.

eined
rcelain
d fret-
ork.

A peculiar kind of glaze or varnish, we are informed, is obtained from white flint. This glaze, it is said, has the singular property of making the pieces of porcelain to which it is applied exhibit the appearance of veins distributed in all directions. Vessels glazed with this material seem as if the surface were cracked, without the fragments being separated or displaced. The colour of this glaze is whitish gray; and when it is applied to porcelain having an azure blue ground, it communicates a beautifully-variegated appearance. Vases of Chinese porcelain are sometimes fabricated in a different manner. They are ornamented with a kind of fret-work, which has something of the appearance of fine lace, in the middle of which is placed a cup proper for holding any liquid; which constitutes one body with the surrounding fret-work.

ingular
ind of
orcelain.

We are informed that the Chinese workmen formerly possessed the secret of fabricating a kind of porcelain of a much more singular nature. On the sides of the vessel thus formed were painted the figures of fishes, insects, and other animals, which could not be seen unless the vessel was filled with water. It is said that this secret is in a great measure lost; but the following is given as part of the process of preparing this kind of porcelain. The vessel which is to be painted, for the purpose of producing this peculiar effect, must be extremely thin and delicate. When it is dry, the colour is laid on, not upon the outside, however, as is usually the case, but upon the inside of the vessel; and it is laid on pretty thickly. The figures which are painted upon it are usually fishes, as being more characteristic of the element in which they live. When the colour is perfectly dry, it is then coated over with a kind of glaze, composed of porcelain earth, so that the azure is thus enclosed between two layers of earthy matter; and when the glaze becomes dry, the workman pours some oil into the vessel, and putting it upon a mould, applies it to the lathe. Porcelain fabricated in this manner, having received its consistence and body within, it is the object of the workmen to make it as thin as possible on the outside, without penetrating to the colour. The external surface is then dipped into a mixture for glazing, and when it is dry it is baked in a common furnace. This kind of porcelain is known by the name of *kia-tsing*, signifying pressed azure. It is supposed that the Chinese do not at present possess the art of making porcelain of this description, which requires a great deal of dexterity and delicate management; and it is added, that they have imperfectly succeeded in the attempts which have been occasionally made to discover the secret of this curious process.

Chinese furnaces.

The next process in the manufacture of porcelain is baking; but before we describe the method of arranging and managing the furnaces employed for this purpose, we shall give a short account of their construction. The Chinese furnaces for baking porcelain are furnished with a long porch, for the purpose of conveying air, and in some measure as a substitute for bellows. This porch answers the same purpose as the arch of a glass-house; but the furnaces which, as the author from whom the account is taken observes, were formerly only six feet in height, and the same in length, are now constructed upon a much more extensive plan. They are twelve feet in height, and nearly four in breadth; and the roof and sides are so thick, that the powerful heat which is applied internally does not penetrate to the outside, at least so much as to be inconvenient to bear it on the application of the hand. The dome or roof is in the form of an inverted funnel, having a large aperture at the top by which the smoke escapes. Beside the principal aperture, there are five others of smaller dimensions, which are covered with broken pots in such a manner that the workman can increase or diminish the heat as he finds it necessary. Through these apertures also he is able to see the progress of the baking of the porcelain, and can judge when it is completed. By uncovering the hole which is nearest the principal opening, he opens with a pair of pincers one of the cases containing the pieces of porcelain, and if he perceives a bright fire in the furnace, and all the pieces brought to a red heat, as well as the colours of the porcelain appearing with a full lustre, he concludes that the process is finished. He then diminishes the fire, and entirely shuts up the mouth of the furnace for some time. In the bottom of the furnace there is a deep hearth about two feet in breadth, over which a plank is laid, in order that the workmen may enter to arrange the porcelain. When the fire is kindled on the hearth, the mouth of the furnace is immediately closed up, and an aperture is left only sufficient for the admission of faggots, about a foot in length, but very narrow. The furnace is first heated for a day and a night, after which two men keep continually throwing wood into it, and relieve each other by turns. One hundred and eighty loads are consumed for one baking. As the porcelain is burning hot, the workman employs for the purpose of taking it out, long scarfs or pieces of cloth, which are suspended from his neck.

Method of baking porcelain.

Having thus given a concise account of the construction of the Chinese furnaces, we proceed now to lay before our readers an account of the method of baking porcelain which is followed in that country. After the porcelain has received its proper form, its colours, and all the intended ornaments, it is transported from the manufactory to the furnace, which is sometimes situated at the other end of the village already mentioned. In a kind of portico, which is erected before it, may be seen vast numbers of boxes and cases made of earth, for the purpose of inclosing the porcelain. Each piece, however inconsiderable it may be, has its own case; and the Chinese workman, by means of this procedure, imitates nature, which, in order to bring the fruits of the earth to maturity, clothes them in a covering, to defend them from the excessive heat of the sun during the day, and from the severity of the cold during the night.

A layer of fine sand is put into the bottom of these boxes, which is covered over with the powder of kaolin, to prevent the sand from adhering too closely to the bottom of the vessel. The piece of porcelain is then placed upon this bed of sand, and pressed gently down, in order that the sand may take the form of the bottom of the vessel, which does not touch the sides of its case; but the case has no cover.

A second, prepared in the same manner, and containing its vessel, is fitted into the first, so that it entirely shuts it, without touching the porcelain which is below; and thus the furnace is filled up with piles of cases, which defend the pieces they contain from the direct action of the fire.

With regard to small pieces of porcelain, such as tea-cups, they are inclosed in common cases about four inches in height. Each piece is placed upon a saucer of earth about twice as thick as a crown piece, and equal in breadth to its bottom. These small cases are also sprinkled over with the dust of the kaolin. When the cases are large, the porcelain is not placed in the middle, because it would be too far removed from the sides, and consequently from the action of the fire.

These piles of cases are put into the furnace, and placed upon a bed of coarse sand six inches in thickness; those by which the middle space is occupied are at least seven feet in height. The two boxes which are at the bottom of each pile remain empty, because the fire acts too feebly upon them, and because they are partly covered by the sand. For the same reason, the case which is placed at the top of each pile is also allowed to remain empty. The piles containing the finest porcelain are placed in the middle part of the furnace; the coarsest are put at its farthest extremity; and those pieces which have the most body and strongest colouring are near its mouth. These different piles are placed very closely in the furnace; and they materially support each other by pieces of earth, which bind them at the top, bottom, and middle, but in such a manner, that a free passage is left for the flame to insinuate itself everywhere around them.

Different kinds of porcelain.

The Chinese divide their porcelain into several kinds or classes, distinguishing each according to the different degrees of beauty and fineness. The whole of the first or most perfect kind is reserved for the emperor; none of it, we are assured, ever comes into the hands of the public, unless, on account of blemishes or imperfections, it is unworthy of being presented to the sovereign. Many have doubted whether at any time the largest and finest porcelain of China has ever been brought to Europe. None of that kind, at least, is offered for sale at Canton. The Chinese, who are apt to undervalue the productions of other countries, entertain a favourable opinion of the Dresden porcelain, and hold in still higher estimation the porcelain which is produced in the French manufactories.

Sir George Staunton's account of the manufacture of porcelain in China.

The following is a short account of the Chinese porcelain manufactures by Sir George Staunton. "From the river," says he, "were seen several excavations made in extracting from the sides of the adjoining hills, the petuntse useful in the manufacture of porcelain. This material is a species of fine granite, or compound of quartz, feldspar, and mica, in which the quartz seems to bear the largest proportion. It appears from several experiments, that it is the same as the growan stone of the Cornish miners. The micaceous part, in some of this granite from both countries, often contains some particles of iron, in which case it will not answer the potter's purpose. This material can be calcined and ground much finer by the improved mills of England, than by the very imperfect machinery of the Chinese, and at a cheaper rate than the prepared petuntse of their own country, notwithstanding the cheapness of labour there.

"The kaolin, or principal matter mixed with the petuntse, is the growan clay also of the Cornish miners. The whashe of the Chinese is the English soap-rock; and the shekan is asserted to be gypsum. It was related by a Chinese manufacturer of that article, that the asbestos, or incombustible fossil stone, entered also into the composition of porcelain. A village, or unwalled town, called Kin-te-chin, was not very far distant from this part of the present traveller's route, in which 3000 furnaces for baking porcelain were said to be lighted at a time, and gave to the place at night the appearance of a town on fire. The genius or spirit of that element is indeed, with some propriety, the principal deity worshipped there. The manufacture of porcelain is said to be precarious, from the want of some precise method of ascertaining and regulating the heat within the furnaces, in consequence of which their whole contents are baked sometimes into one solid and useless mass. Mr. Wedgwood's thermometer, founded on the quality observed by him, of clay contracting in proportion to the degree of fire to which it is exposed, might certainly be of use to a Chinese potter."

2. *Inquiries of Reaumur into the Nature of Porcelain.*

Compos- tion of p celain ex mined.

The first scientific investigation which was made into the nature of porcelain, was undertaken by the celebrated Reaumur; and the result of his researches was communicated to the French Academy of Sciences in the years 1727 and 1729. It was not the external form or appearance, nor was it the decorations of painting and gilding, which are by no means essential to porcelain, that constituted the object of his inquiries. His examination was particularly directed to the peculiar texture and fabric of this substance, with the view of ascertaining the nature and proportions of its constituent parts. For this purpose, he broke to pieces some of the Japanese, the Saxon, and the French porcelains, and carfully noted the peculiarities and differences in their texture. The grain or texture of the Japanese porcelain appeared to possess a considerable degree of closeness and compactness, with a smooth and somewhat shining aspect. He found that the Saxon porcelain was still more compact, and that it was smooth, and shining like enamel, but had nothing whatever of the granular texture. In his examination of the French porcelain, he observed that it had much of the shining appearance, and that its grain was not so close and fine as that of the oriental porcelain, having some resemblance to the grain or texture of sugar. Such were the observations which occurred to the French philosopher at the commencement of his inquiries into the nature of porcelains; and hence he justly concluded, that they were characterised by very marked differences.

Effects o heat on porcelain

Proceeding in his investigation, the same philosopher subjected different porcelains to the action of heat; and the result of his experiments with this powerful agent proved, that they might be distinguished by still more decisive characters. It appeared that the porcelain of the East suffered no change from the action of the greatest heat, whereas that of European manufacture underwent fusion at no very high temperature. This remarkable difference between the Chinese and European porcelains, suggested to Reaumur an ingenious thought, which at last led him to the discovery of the true nature of the composition of porcelain. Having observed that all porcelains have some resemblance to glass in some of their general properties, although they are less compact, he considered them as in the state of a semi-vitrified substance. An earthy substance, he observed, may be in a semi-vitrified state in two ways. It may, in the first place, be entirely composed of vitrifiable or fusible matters; and this being the case, when it is exposed to the action of fire, provided the heat be sufficiently strong and long continued, it will be melted or vitrified. But as this change is not effected instantly, particularly where a violent degree of heat is not applied; and as it passes through different degrees, the progress of which may be more easily observed, according as the heat is managed and regulated, it followed, that by stopping in proper time the application of the heat to porcelain prepared in this way, the ware may be obtained in an intermediate state between those of crude earths and completely vitrified substances; whilst, at the same time, it possesses the semitransparency and other distinguishing properties of porcelain. Porcelain of this nature, it is well known, being exposed to a stronger degree of heat, undergoes perfect fusion and complete vitrification. All the European porcelains which were subjected to experiment by Reaumur, were found to be of this fusible nature.

Porcelain composed of fusible and infusible matter.

But on the other hand, porcelain may be composed of fusible or vitrifiable matter, mixed in certain proportions with another matter, which is absolutely infusible in the strongest heat to which it can be exposed in the furnace; and hence, if a mixture of this kind be subjected to a heat sufficient to melt entirely the vitrifiable part of its composition, this will enter into fusion; but being mixed with another matter which is infusible, and which consequently retains its consistency and opacity, the whole will form a compound, partly opaque, and partly transparent, or, in other words, a semitransparent mass; that is, a semivitrified substance, or porcelain, but possessing qualities totally distinct from those of the former. For as the fusible part of the latter has been brought to its utmost degree of fusibility during the process of baking, although the compound may be exposed a second time to a still stronger degree of heat, it will not approach nearer to complete vitrification, that is, it will retain all the qualities of perfect porcelain. Reaumur found that the porcelain of the East was distinguished by the properties now described; and hence he concluded, that its component parts were arranged upon the principle above mentioned. This opinion was afterwards confirmed by incontrovertible facts, deduced from a train of the most satisfactory and well directed experiments.

Kaolin infusible, and petuntse a vitrifiable matter.

The ingredients which enter into the composition of the Chinese porcelain, namely, the petuntse and kaolin, were the next object of Reaumur's inquiries. Having obtained quantities of each, he subjected them separately to a strong heat, and he found that the petuntse entered into fusion, without addition; but it appeared that the kaolin was absolutely infusible. He then mixed the two ingredients, formed into cakes, and exposed them in a furnace to the proper degree of heat; so that by baking they were converted into porcelain exactly similar to that of the Chinese. From these experiments it appeared, that the petuntse of the Chinese was a vitrifiable substance, and that the kaolin was of a different nature, quite refractory, and totally infusible. After this discovery, Reaumur, it would seem, entertained hopes that he might find materials in France, capable of making porcelain, which should possess the same valuable qualities as that of China; but whether his researches in the discovery of proper materials in his own country, particularly that which corresponds to the petuntse of the Chinese, were baffled, or whether he was prevented by other avocations from prosecuting his inquiries, does not appear. In his second memoir upon porcelain, however, we find, that he afterwards attempted to compose an artificial petuntse, by mixing vitrifiable stones with such saline bodies as were capable of rendering them fusible, or even by substituting for this artificial preparation glass ready formed, with the addition of such matters as he supposed might be successfully employed in the place of kaolin. But it would appear that he did not at the time prosecute his inquiries; for the subject was not resumed until the year 1739, when he announced the discovery of a process for converting common glass into a peculiar kind of porcelain, which has been since known by the name of *Reaumur's porcelain.*

Mistakes of Reaumur.

Although it must appear, from the detail now given, that Reaumur was directed in his researches by the true spirit of philosophical inquiry, he seems to have been misled in certain points. One of his errors was relative to the Saxon porcelain, which he confounded with the other fusible porcelains of European manufacture, unless it be supposed that the porcelain of Saxony was formerly composed of entirely fusible or vitrifiable matters, and that it was porcelain of this description which he examined; for it is now certain, that all the porcelain of that country is capable of resisting the most powerful heat, and is therefore equally infusible with that of China or Japan. The appearance of the internal texture of the Saxon porcelain may perhaps have led the philosopher to this erroneous conclusion; for when it is broken, the internal surface does not exhibit a granular texture, but is uniform, smooth, shining, and compact, having a great resemblance to white enamel. This appearance, however, so far from proving that the porcelain of Saxony is a fused or vitrified substance, shews that it is not entirely composed of fusible matters. The internal surface of the most fusible porcelains, it is well known to those who are acquainted with the subject, is also the least dense, and the least compact; for no vitreous matter can be internally smooth and dense, without having been in a state of complete fusion.

The Saxon, like every other porcelain, especially that of China and Japan, contains a fusible substance, which has been in a state of complete fusion during the process of baking. The density and the internal lustre depend chiefly on this fused matter; but it is also certain, that the Saxon porcelain contains a large proportion of a substance which is absolutely infusible, and from which it derives its beautiful white appearance, its firmness and solidity, during the process of baking. It is this infusible substance which is to be considered as the substitute for the kaolin of China, and which possesses the property of contracting its dimensions, whilst it unites with the fusible material. The Saxon porcelain, therefore, is not to be confounded with porcelain manufactured with vitreous and fusible material; for it seems to be equally excellent as that of Japan, and in some of its properties perhaps superior, as will appear from an examination of the qualities which constitute the peculiar excellence of porcelain.

Reaumur seems likewise to have taken an erroneous view of the nature of the Chinese kaolin. According to his account, this matter is a fine talcky powder, from the mixture of which with petuntse, the porcelain of the East is manufactured. It is not impossible, as has been observed, that a porcelain similar to the Chinese might be produced from a talcky substance of this nature mixed with petuntse; but it is well known to those who are at all familiar with the manufacture of any porcelain, that no vessels can be formed, unless the paste of which they are made possess that degree of ductility and tenacity which renders them fit for being worked upon the lathe, or fashioned in the mould. But substances of a talcky nature, to whatever degree of fineness they may be reduced, never acquire the requisite ductility and tenacity which clays of all earthy substances only possess. But as it appears that the Chinese porcelain has been turned upon the lathe, it is obvious that they must have been formed of a very tenacious paste; and hence it is concluded, that kaolin is not purely a talcky matter, but an infusible clay, which, with the petuntse, a fusible material, forms the ingredients which enter into the composition of Chinese porcelain.

3. *Peculiar Properties of Porcelain.*

Essential qualities of porcelain.

It may be worth while now to consider what are the properties which constitute the perfection of porcelain; and here it is necessary carefully to discriminate between the qualities which are to be regarded as only contributing to the external decoration, and the intrinsic and essential properties in which the fabric and perfection of porcelain consist. Those who have been occupied in experiments upon this subject, have not found it difficult to form compositions which are very white, beautifully semi-transparent, and covered with a shining glazing, but which are extremely deficient in the more essential properties. It appears, indeed, that they cannot be subjected to the necessary operations in first forming the ware, for want of a proper degree of tenacity, that they are not sufficiently compact, and are quite fusible, subject to break by the sudden application of heat or cold, and from the softness of the glazing, which cracks and becomes rough, are soon deprived of their lustre. On the other hand, it is by no means difficult to form compositions of pastes, which are very tenacious, and which are capable of being easily worked and well baked, and in the process of baking which acquire the requisite degree of hardness and density; which are infusible, and capable of resisting the effects of sudden changes of heat and cold; and which, in short, possess all the qualities of the most excellent porcelain, excepting its whiteness and transparency. Materials fit for the composition of such porcelains, it will appear, may be found in abundance in most countries; but those fit for the manufacture of the finer and more perfect porcelains, seem to be sparing productions of nature; and therefore the best kind of porcelain, it is presumed, will always be regarded as a valuable and high-priced commodity.

Nature of stoneware.

It may be observed that the potteries called *stoneware*, such as the brown made at Lambeth and some other places, and the white formerly made at Burslem in Staffordshire, which were glazed by salt, or muriate of soda, being thrown into the furnace when in a state of high fusion, possess all the essential qualities of the Japanese porcelain; for, excepting the whiteness, on which alone the semitransparency depends, if we compare the properties of the Japanese porcelain with those of our stoneware, little difference is found to exist between them. Both seem to possess the same granular texture; both have the same sonorous quality, when struck with a hard body; both have the same density; they possess also the same hardness, by which they strike fire with steel; they can resist the effects of the heat of boiling liquors without breaking, and are equally infusible when subjected to the most violent heat. Hence it is inferred, that if the earth which enters into the composition of stoneware, were free from foreign colouring matters, which prevent the whiteness and semitransparency, and if the vessels were carefully formed and covered with a very fine glaze, they would not be less perfect than the porcelain of the East. (See POTTERY.) Earths fit for the production of the more perfect kinds of porcelain are supposed to be more rare in Europe than in Japan and China; and hence probably it has happened, that, from the want of these earths, the first manufacturers of the porcelain in Europe confined themselves to an external imitation, by employing only vitrifiable matters with fusible salts, and small quantity of white earth, of which fusible and vitreous porcelains were composed.

One of the most valuable qualities of porcelain is the property of resisting sudden alternations of heat and cold, in which the European porcelain exceeds that of China or Japan. The quality of porcelain, it is to be observed, is not to be judged of by a slight trial; for as numerous circumstances concur to render a piece of porcelain capable or incapable of resisting the effects of heat or cold, boiling water may be at the same time poured into two vessels, one of which is good porcelain, and the other of an opposite quality, it is not impossible that the former may break, and the latter may remain entire. The true method of discovering what is good porcelain, is to examine several pieces which are in daily use; and it has been found, that in many pieces of porcelain of oriental manufacture, which have been long used, cracks are seen in the direction of their height, which are never perceived in the more perfect porcelains of European manufacture.

Japanese porcelain formerly reckoned the most perfect.

It has long been a very general opinion, that the Japanese porcelain is the most perfect; it has indeed continued to be the object of admiration and emulation, and has been held up as a model for the European manufacturer. But the taste of Europeans having required a porcelain possessing the qualities of transparency and whiteness in a greater degree than that of Japan, the attempts to imitate it have been mostly confined to experiments. It has therefore been erroneously contended that an article equal to the Japan porcelain cannot be produced in Europe. The Saxon porcelain has been considered as inferior to the Japanese, on account of its greater smoothness, lustre, and less granular aspect of its internal texture; qualities in which it ought really to be regarded as superior to the porcelain from Japan.

4. *Porcelain Manufactories in different parts of Europe.*

Manufactories of porcelain have been long established in almost every country of Europe, but from the experiments of Reaumur it would appear that the only kind then manufactured was the soft porcelain, or *porcelaine tendre*. It has been seen that the Saxon manufacturers charged him with mistake in classing theirs with the soft porcelain; but by admitting that he might have operated upon an article formerly made by them, it is proved that all European porcelain was originally of this kind. Besides that of Saxony, which was the first established in Europe, porcelain is made to a considerable extent at Vienna, at Frankendal, in the neighbourhood of Berlin, and in other places in the German states. The German porcelains are similar to those of Saxony, and are composed of similar materials, although from certain differences in the proportions, or in the modes of managing the manufactories, considerable differences arise in the porcelains manufactured at different places. When M. de la Condamine travelled into Italy, he visited a manufacture of porcelain established at Florence by the Marquis de la Ginor, who was at that time governor of Livorno. The French traveller was particularly struck with the large size of some of the pieces of this porcelain. Statues, and even groups of figures half as large as nature, and modelled from some of the finest antiques, were formed of it. The furnaces, he observed, in which the porcelain was subjected to the process of baking, were constructed with a great deal of ingenuity, and were lined with bricks made of the same materials as those which entered into the composition of the porcelain itself; and hence they were able to resist the effects of high degrees of heat. The paste of the porcelain manufactured at Florence appeared to be extremely beautiful, and to possess all the qualities of the best oriental porcelain. The glazing employed in this manufactory seemed to be inferior in whiteness, a circumstance which is supposed to be owing to the desire of using those materials only which are found in the country.

Manufactures of porcelain in France.

It must be allowed that the labours of the French have been crowned with wonderful success in the improvement and perfection of this manufacture. Some time before even Reaumur communicated the result of his inquiries, porcelain was manufactured at St. Cloud, and also in the suburb of St. Antoine at Paris. This porcelain indeed was of the vitreous or fusible kind, but at the same time it possessed no inconsiderable degree of beauty. Since the period to which we allude, extensive manufactories of porcelain have been established at Villeroy, Chantilly, and Orleans, and at those places the manufacture has been brought to a high degree of perfection. But the great seat of the manufacture is now in the Limousin, where the raw materials are found, and whence the porcelain in a white state is sent to Paris and other places on the continent, to be ornamented. The productions of the celebrated royal porcelain manufactory at Sèvres, near Paris, on account of the pure shining white, the fine glazing and coloured grounds, the splendour and magnificence of the gilding, and the elegance and taste displayed in the shape and figures, are universally allowed to surpass every thing of the kind which has yet appeared. It must be remarked, however, that this manufactory at Sèvres, wherein the "*porcelain dure*" is produced in so great a degree of perfection, is not carried on with a view to profit, but has received occasional grants of money from the government, as a national concern.

In speaking of the French porcelain, we may notice the result of some researches which were made on this subject by Guettard, and of which an account appeared in the Memoirs of the Academy of Sciences, for the year 1765. In the neighbourhood of Alençon, M. Guettard discovered a whitish argillaceous earth, in which he found that mica considerably predominated. This earth he employed as a substitute for kaolin. The substance which he used instead of the petuntse, he obtained from a hard stone, which is described as a quartzose gritt stone, very abundant in that country, and with which the streets of Alençon are paved. With these materials Guettard instituted a series of experiments on porcelain, previously to the year 1751, and was associated in his inquiries with the Duke of Orleans. For many years the Count de Lauraguais, a member of the Academy of Sciences, was keenly engaged in prosecuting experiments to discover the true nature of porcelain, and the means by which the manufacture might be improved and perfected. To obtain the object of his researches, which was to produce porcelain that in its essential qualities might be equal to that of eastern countries, he spared no trouble or expense; and it would appear that he was not unsuccessful in his labours; for in the year 1766, when he exhibited some species of porcelain from his manufactory to the members of the Academy of Sciences, the persons who were appointed by that learned body to examine their properties, delivered it as their opinion, that of all the porcelain made in France, that of the Count de Lauraguais approached most nearly in the essential properties of solidity, texture, and infusibility, to that of China and Japan. It is said, however, that it was considerably deficient in whiteness and lustre, when compared with the ancient porcelain of Japan. The great interest, however, created in France in support of this elegant and useful fabric, the continued experiments of the ablest chemists and scientific men, with the discovery of better materials which are abundant in the South of France, gave to that country facilities which enabled her soon to take the lead of the continent and of Britain in the production of this article.

Manufactory at Tournay.

Porcelain manufactories have long been established at Tournay in Flanders. One of these manufactories furnishes all Flanders with blue and white porcelain. At this manufactory they have a particular process in forming cups and other vessels. They are neither turned on the lathe, nor is the clay compressed in a mould; but after being diluted in water, and when the liquid has acquired a proper consistency, the workmen pour it into moulds, two or three hundred of which are arranged together. When they have filled them all, they return to the first in the row. The liquid part is drawn off by a gentle inclination; the surplus adheres to the side of the vessel, and thus forms the piece which it is intended to make. The piece is detached from the mould by means of a slight stroke; and after being sufficiently dried, it is conveyed to the furnace, to undergo the process of baking.

In England

In England but little progress was made in the manufacture of porcelain, until towards the end of the last century. At an earlier period there was a manufactory carried on by some Germans at Chelsea, afterwards removed to Derby, of porcelain of a very superior quality; but whence they derived their materials is now uncertain. The porcelain which was then made at Liverpool, and some other places, was of an inferior kind, and manufactured so thin, in order to procure transparency, as to render it in a great degree unserviceable. This porcelain was made of the clays from Devonshire, to which a frit, described hereafter, was added to improve the colour of the body, and to create that degree of transparency which was required by the public as a principal attribute of porcelain.

About the year 1768, the discovery in Cornwall of mines of clay and stone similar to those used in France and Germany, and which are believed to be the kaolin and petuntse of the Chinese, soon enabled the English manufacturer to improve his porcelain, by discontinuing the use of frit, or glass, as a component part of the basis or body of the ware, and substituting a mixture of the fusible and infusible earths as the basis of his porcelain, as had been done, at a much earlier period, in Germany and France. And thus the English porcelain, in many of its essential qualities, particularly in the beauty and richness of its paintings and gildings, as well as the elegance of its forms, has become little, if at all inferior, to that of any other country.

There are in England a number of manufactories of porcelain, at Derby, at Worcester, at Coalbrookdale, and at Rotherham, in Yorkshire. But the principal site of this manufacture is now in the Staffordshire Potteries, where it is produced in large quantities, at various manufactories.

5. *Different Processes in the Manufacture of Porcelain.*

Bases.

The basis of those porcelains which were respectively known by the name of *vitreous*, *fusible*, and *soft* porcelain, was in part composed of what was called a *frit*; that is to say, a mixture of alkalis and siliceous earths, brought into fusion, which, forming an opaque glass, was ground very fine, and mixed with an infusible earth or clay, in quantity sufficient to produce a degree of fusion, and consequent transparency of the whole body, but not so much as to prevent the ductility necessary for the formation of the articles to be made. The basis of the porcelains now generally made is composed of a mixture of infusible and fusible earths, in those proportions which, on the application of intense heat, produce that transparency and semi-vitrification which is required as the distinguishing properties of porcelain.

Manipulation.

Up to a certain point, the operations and manipulations are the same in all cases. The clay or infusible earth having been separated by washing from the mass of decomposed granite, of which it forms a part, is mixed with a portion of the fusible earth, finely livigated into a liquid of the consistence of cream, which, after being passed through the finer silk lawns, is placed on kilns to evaporate the superfluous water, until the mass becomes a soft tenacious paste, ready for the operations of the workman. It is then taken to the thrower, to be fashioned on his wheel; and having obtained a sufficient degree of hardness to preserve its form, is transferred to the lathe to be more correctly shaped, and the surface made even. It next has handles, feet, and other requisites added, and is then ready to receive its first firing. To effect this, it is, when sufficiently dry, put into a case made of earthen ware, and placed in the furnace, that it may be subjected to the process of baking. These cases are known amongst the English potters by the name of *seggars* or *saggars*, and they are generally formed of a coarser kind of clay; but this clay must possess the property of resisting the action of heat necessary for the baking of porcelain, without being fused. The porcelain contained in the cases is thus protected from the smoke of the burning fuel. The whiteness of the porcelain depends greatly on the purity of the clay of which the *saggars* are made, so that being of a more compact texture, the smoke is more effectually excluded. These cases are arranged in the furnace or kiln in piles, one upon the other, to the top of the furnace.

A small fire is first made, that the furnaces may be gradually heated; and it is increased more and more until the process of baking is completed, that is, until the porcelain shall have acquired a proper degree of hardness and transparency. To ascertain this point, much attention is necessary, by taking out of the furnace from time to time, and examining, small pieces of porcelain placed for that purpose in some cases, which have lateral openings in the walls of the furnace to render them accessible. When it appears, from the examination of those pieces, that the porcelain is sufficiently baked, the fire is no longer to be supplied with fuel; the furnace is allowed to cool gradually, and the porcelain is afterwards taken out.

But at this point of the process of baking, or firing, the modes adopted in France, and on the continent generally, are materially different from the practice in this country; in fact, are totally reversed. In England the first, or biscuit firing, is employed to produce, by an intense heat, the required degree of transparency and vitrification; whilst in France but a small degree of heat is applied, sufficient only to harden *(degourdir)* the ware, so that it may bear the manipulation necessary before the glazing, without breaking, the transparency and strength being obtained at the second operation of firing, which, like the English biscuit-firing, requires an intense heat to accomplish that object.

Unglazed porcelain called biscuit.

Unglazed porcelain has the appearance of white marble, having nothing of that shining surface which it acquires by covering it with the vitreous composition called glaze, and is said to be in the state of *biscuit*. For particular purposes, the porcelain is sometimes allowed to remain in this state, and particularly when it is employed in smaller and finer pieces of sculpture, where the fineness of the workmanship and the sharpness of the figures are wished to be preserved, as it is well known that these will be greatly injured by being covered with a coat of glazing. The celebrated manufactory of Sèvres has long been distinguished for figures or small statues, and even for larger works, as ornamental vases, &c., which are left in the state of biscuit. The English manufactories are probably not inferior in the delicacy and accuracy of execution of ornamental productions of this kind.

Method of glazing porcelain.

The next operation in the manufacture of porcelain is the process of glazing. This process consists in covering the porcelain with a thin coat of vitreous or fusible matter, which adds greatly to its beauty, by its lustre or shining appearance. In preparing and applying the materials fit for glazing porcelain, it has been found that the same mixture will not admit of general application; for it appears, that what forms a fine glazing for one kind of porcelain, will not answer the same purpose when applied to another. In the former it may have all the necessary requisites, but in the latter it may crack in many places, may have no lustre, and may contain bubbles, or be apt to scale off. The first thing, then, is to prepare a glaze which shall be suited to the nature of the porcelain for which it is intended. The glazing must be appropriated to each kind of porcelain, that is, to the ingredients which enter into its composition, or to the degree of hardness or density of the ware. The materials of which the glazing is composed are prepared by previously fusing together all the substances of which they consist, and thus forming a vitreous mass. This mass of vitrified matter must be finely ground in a mill, and the vitreous powder thus obtained be mixed with a sufficient quantity of water, so that the liquor shall have the consistence of cream of milk. The pieces of porcelain are to be covered with a thin coating of this matter, which is done by immersing them hastily in the liquid, and as they greedily imbibe the water, there remains on the surface a uniform covering of the glazing materials. This covering, which, it must be observed, should be very thin, in a short time becomes so dry, that it does not adhere to the fingers when the pieces are handled. When they are sufficiently dry, they are replaced in the furnace in the same manner as in preparing the biscuit, and the heat is continued till the glazing be completely fused; but the degree of heat necessary for that purpose is far inferior to that which is requisite in baking the paste. As before noticed, however, this does not apply to the French porcelains, the glazing of which is effected by a higher degree of heat than what is applied to the paste or body.

The glaze used for the soft porcelain possessed great advantages in the execution of the more delicate paintings and decorations, by its property of assisting to flux and fix with more certainty the metallic oxides of which the colours are composed. The old Sèvres china is of this description. But at that royal manufactory, under the able direction of M. Brogniat, the *porcelaine dure*, now the only kind made there, has been so much improved, as to admit of its being embellished by paintings of the most delicate and brilliant colours and superb grounds, with gilding equal, if not superior, to the old Sèvres.

Of painting.

The pieces of porcelain which are intended to remain white are now finished, but those which are to be ornamented with painting and gilding must go through various other operations. The colours which are employed in painting porcelain on the glaze are similar to those which are applied in the painting of enamel. They are all composed of metallic oxides or calces, combined with a very fusible vitreous matter. The different colours are obtained from different metals. The oxides of iron afford a red colour; gold, precipitated by means of tin, furnishes a purple and violet colour; copper, precipitated from its solution in acids by means of an alkali, gives a fine green; cobalt, or when combined with vitreous matter, *zaffar*, as it is called, yields a fine blue. Earthy matters which are slightly feruginous, produce a yellow colour; and brown and black colours are obtained from iron in different states, and from manganese. The oxide of chrome, which has but lately come into use, has furnished artists with greens and some other colours, of a brilliancy and fixedness in the fire not before known. These colours are applied to the ware by the painters according to the requisite pattern, and it is again conveyed to the furnace, and the colours are vitrified, to give them the proper degree of fixation and lustre. In the common kind of porcelain, once or twice burning is sufficient, but in the finer decorations the colours must be laid on several times, and as often fired before the full effect can be produced. This process is similar to that practised by enamellers on copper, &c.; but the blue colour from cobalt is much used for painting on the biscuit ware before glazing.

Of printing.

The discovery of a method of imitating the painted patterns of the Chinese by impressions taken from engraved copper plates, was of great importance, as it enabled the European manufacturers to compete with the cheap labour of the Chinese. This discovery is due to a manufacturer at Liverpool, where porcelain was formerly made. The process is as follows. The pattern being engraved on a copper plate of the size wanted, it is charged with the colour to be used, which is mixed with boiled linseed oil; the plate is then placed on a hot stove, and a piece of thin tissue paper, previously primed with a solution on one side of soft soap, is laid upon the plate, and both passed through the rollers of the press as in ordinary printing. The impression is then taken off, and transferred on to the ware. After being well rubbed with a roller of flannel, to cause the colour and oil to adhere to the ware, the piece is then put into lukewarm water, where the paper, by the action of the soap, leaves the ware and the colour upon it. The ware is next dried, and subjected to a degree of heat, to evaporate the oils, and the ware is then in a condition for the glazing.

Gilding.

But when the pieces of porcelain are to be further decorated with gilding, they are pencilled with a mixture of oil and gold, dissolved or thrown down by quicksilver with the aid of heat, and are again introduced into the furnace. Here the gold returns to its solid state, but comes out with a dull surface; and to recover its lustre and usual brilliancy, it is burnished with blood-stones, and other polishing substances. Much care and attention are necessary in the latter part of the process; for if the gold be not sufficiently burned, it will be apt to separate in thin flakes; and if it have been exposed to too great a heat, it is not susceptible of a fine polish. In this manufactory, when pieces of porcelain are to be finished in the highest style, they are frequently returned to the enamel furnace, where the colours are fluxed six or seven different times; and having gone through the processes now described, the porcelain is fit for the market.

Use of platina in colouring porcelain.

The use of platina in porcelain painting has been recommended by Klaproth; and experiments have been made on the subject by that celebrated chemist, with the view of ascertaining its effects for this purpose. In concluding his observations, he says, "The process which I employ in the application of platina to painting on porcelain is simple and easy. I dissolve crude platina in aqua regia, and precipitate it by a saturated solution of sal-ammoniac in water. The red crystalline precipitate thence produced is dried, and being reduced to a very fine powder, is slowly brought to a red heat in a glass retort. As the volatile neutral salt combined with the platina in this precipitate becomes sublimated, the metallic part remains behind in the form of a gray soft powder. This powder is then subjected to the same process as gold; that is to say, it is mixed with a small quantity of the same flux as that used for gold, and being ground with oil of spike, is applied with a brush on the porcelain; after which it is burned-in under the muffle of an enameller's furnace, and then polished with a burnishing tool.

"The colour of platina burnt into porcelain in this manner is a silver white, inclining a little to a steel gray. If the platina be mixed in different portions with gold, different shades of colour may be obtained; the gradations of which may be numbered, from the white colour of unmixed platina to the yellow colour of gold. Platina is capable of receiving a considerable addition of gold before the transition from the white colour to yellow is perceptible. Thus, for example, in a mixture of four parts of gold and one of platina, no signs of the gold were to be observed, and the white colour could scarcely be distinguished from that of unmixed platina: it was only when eight parts of gold to one of platina were employed that the gold colour assumed the superiority.

"I tried in the like manner different mixtures of platina and silver; but the colour produced was dull, and did not seem proper for painting on porcelain.

"Besides this method of burning-in platina in substance on porcelain, it may be employed also in its dissolved state; in which case it gives a different result both in its colour and splendour. The solution of it in aqua regia is evaporated, and the thickened residuum is then applied several times in succession to the porcelain. The metallic matter thus penetrates into the substance of the porcelain itself, and forms a metallic mirror of the colour and splendour of polished steel."

General principles of the manufacture of Porcelain and Earthenware.

Convinced that every accurate and scientific investigation into the nature and processes of any important art, will always be deemed of some value to the philosophical observer, or the enlightened manufacturer, we shall introduce the following observations on the principles of the manufacture of porcelain and earthenware.

Observations by Vauquelin.

Component parts of porcelain and pottery ware.

According to this celebrated chemist, four things may occasion differences in the qualities of earthenware; first, the nature or composition of the matter; second, the mode of preparation; third, the dimensions given to the vessels; fourth, the baking to which they are subjected. By composition of the matter, the author understands the nature and proportions of the elements of which it is formed. These elements in the greater part of earthen ware, either valuable or common, are silex, argil, lime, and sometimes a little oxide of iron. Hence it is evident that it is not so much by the diversity of the elements that good earthenware differs from bad, as by the proportion in which they are united. Silex or quartz makes always two-thirds at least of earthenware; argil or pure clay, from a fifth to a third; lime from 5 to 20 parts in the hundred; and iron from 0 to 12 or 15 parts in the hundred. Silex gives hardness, infusibility, and unalterability; argil makes the paste pliable, and renders it fit to be kneaded, moulded, and turned at pleasure. It possesses, at the same time, the property of being partially fused by the heat which unites its parts with those of the silex; but it must not be too abundant, or it would render the earthen ware too fusible, and too brittle to be used over the fire.

Hitherto it has not been proved by experience that lime is necessary in the composition of pottery; and if traces of it are constantly found in that substance, it is because it is always mixed with the other earths, from which the washings and other manipulations have not been able to separate it. When this earth, however, does not exceed five or six parts in a hundred, it appears that it is not hurtful to the quality of the pottery; but if more abundant it renders it too fusible. The oxide of iron, besides the inconvenience of communicating a red or brown colour, according to the degree of baking, to the vessels in which it forms a part, has the property of rendering them fusible, and even in a greater degree than lime.

Mode of preparation.

As some kinds of pottery are destined to melt very penetrating substances, such as salts, metallic oxides, glass, &c. they require a fine kind of paste, which is obtained only by reducing the earths employed to very minute particles. Others destined for melting metals, and substances not very penetrating, and which must be able to support, without breaking, a sudden transition from great heat to great cold, require for their fabrication a mixture of calcined argil with raw argil. By these means you obtain pottery, the coarse paste of which resembles *brèche*, or small-grained pudding-stone, and which can endure sudden changes of temperature.

Baking.

The baking of pottery is likewise an object of great importance. The heat must be capable of expelling humidity, and agglutinating the parts which enter into the composition of the paste, but not strong enough to produce fusion; which, if too far advanced, gives to pottery a homogeneousness that renders it brittle. The same effect takes place in regard to the fine pottery, because the very minute division given to the earths reduces them nearly to the same state as if this matter had been fused. This is the reason why porcelain strongly baked is more or less brittle, and cannot easily endure alternations of temperature. Hence coarse porcelain, in the composition of which a certain quantity of calcined argil is employed, porcelain retorts, crucibles, tubes, and common pottery, the paste of which is coarse, are much less brittle than dishes and saucers formed of the same substance, but ground with more labour.

Dimensions of the different parts of vessels.

The general and respective dimensions of the different parts of vessels of earthenware, have also considerable influence on their capability to stand the fire. In some cases the glazing or covering, especially when too thick, and of a nature different from the body of the pottery, also renders them liable to break. Thus, in making some kinds of pottery, it is always essential, first, to follow the best proportion in the principles; secondly, to give to the particles of the paste, by grinding, a minuteness suited to the purpose for which it is intended, and to all the parts the same dimensions as far as possible; thirdly, to carry the baking to the highest degree that the matter can bear without being fused; and fourthly, to apply the glazing in thin layers, the fusibility of which ought to approach as near as possible to that of the matter, in order that it may be more intimately united.

M. Vauquelin, being persuaded that the quality of good pottery depends chiefly on using proper proportions of the earthy matter, thought it might be of importance to those engaged in this branch of manufacture, to make known the analysis of different natural clays employed for this purpose, and of pottery produced by some of them, in order that, when a new earth is discovered, it may be known by a simple analysis whether it will be proper for the same object, and to what kind of pottery already known it bears the greatest resemblance.

	Hessian Crucibles.	Argil of Dreux.	Porcelain Capsules.	Wedgwood's Pyrometers.
Silex	69	43.5	61	64.2
Argil	21.5	33.2	28	25
Lime	1	3.5	6	6
Oxide of Iron	8	1.	0.5	0.2
Water	...	18.	...	6.2

Raw kaolin 100 parts; silex, 74; argil, 16.5; lime, 2; water, 7. A hundred parts of this earth gave eight of alum, after being treated with the sulphuric acid.

Washed kaolin, 100 parts; silex, 55; argil, 27; lime, 2; iron, 0.5; water, 14. This kaolin, treated with the sulphuric acid, gave about 45 or 50 per cent. of alum.

Petuntze. Silex, 74; argil, 14.5; lime, 5.5; loss, 6. A hundred parts of this substance, treated with the sulphuric acid, gave seven or eight parts of alum. But this quantity does not equal the loss sustained.

Porcelain of retorts. Silex, 64; argil, 28.8; lime, 4.55; iron, 0.50; loss, 2.77. Treated with the sulphuric acid this porcelain gave no alum.

Porous ware.

There is a kind of earthen vessels, called *Alcarrezes*, which are used in Spain for cooling the water intended to be drunk. These vessels consist of 60 parts of calcareous earth, mixed with alumina and a little oxide of iron, and 36¼ of siliceous earth, also mixed with alumina and the same oxide. The quantity of iron may be estimated at almost one hundredth part of the whole. This earth is first kneaded into a tough paste, being for that purpose previously diluted with water; then formed into a cake of about six inches in thickness, and left in that state until it begin to crack. It is then kneaded with the feet, the workman gradually adding to it a quantity of sea-salt, in the proportion of seven pounds to a hundred and fifty; after which it is applied to the lathe, and baked in any kind of furnace used by potters. The alcarrezes, however, are only about half as much baked as the better kinds of common earthenware; and being exceedingly porous, water oozes through them on all sides. Hence the air which comes in contact with it, by causing it to evaporate, carries off the caloric contained in the water in the vessel, which is thus rendered remarkably cool.

Observations of Brongniart on the Colours used for Enamelling.

Enamel of the ancients.

The art of employing metallic oxides for colouring by fusion different vitreous matters, is of very great antiquity. Every body knows that the ancients manufactured coloured glass and enamel, and that this art was practised in particular by the Egyptians, the first people who in this manner imitated precious stones. The practice of this art in modern times has been carried to a high degree of perfection; but the theory has been neglected. It is almost the only one of the chemical arts in which no attempt has yet been made to apply the new principles of that science. It is well known that all vitrifiable colours have for their basis metallic oxides; but all the metallic oxides are not proper for this purpose; besides, as they are not vitrifiable by themselves, they can scarcely ever be employed alone.

Metallic oxides employed as colours for porcelain.

Highly volatile oxides, and those which adhere little to the great quantity of oxygen they contain, either cannot be employed in any manner, as the oxide of mercury and that of arsenic, or are employed only as agents. The colour they present cannot be depended on, since they must lose it in the slightest heat by losing a part of their oxygen. Such are the puce-coloured and red oxides of lead, the yellow oxides of gold, and some others. Oxides in which the proportions of oxygen are susceptible of varying with too much facility, are rarely employed. The oxide of iron, though black, is never employed for producing that colour; and the green oxide of copper is, under many circumstances, very uncertain. We have said that oxides alone are not susceptible of fusion. However, as they are destined to be applied to thin strata upon vitrifiable substances, they may be attached to them by a violent heat. But, excepting the oxides of lead and bismuth, they would give only dull colours. The violent heat, often necessary to fix them, would change or totally destroy the colours. A flux then is added to all metallic oxides.

This flux is glass, lead, and silex; glass of borax, or a mixture of both. Its general effect is to give splendour to the colours after their fusion; to fix them upon the article which is painted, by promoting more or less the softening of its surface; to envelope the metallic oxides, and to preserve their colour, by sheltering them from the contact of the air; in a word, to facilitate the fusion of the colour at a low temperature not capable of destroying it.

The substances to which they are applied.

But we shall speak here only of the application of metallic colours to vitreous bodies, or to vitreous surfaces. These bodies may be divided into three classes, very distinct by the nature of the substances which compose them, the effects produced on them by the colours, and the changes they experience. These crusts are, first, enamel, soft porcelain, and all crusts, enamels, or glass, that contain lead in a notable quantity; secondly, hard porcelain, or porcelain which has a crust of feldspar; thirdly, glass in the composition of which no lead enters, such as common window-glass. We shall here examine in succession the principles of the composition of these colours, and the general phenomena they exhibit on these three kinds of bodies.

It is well known that enamel is glass rendered opaque by the oxide of tin, and exceedingly fusible by the oxide of lead. It is the oxide of lead, in particular, contained in it, that gives it properties very different from those of the other excipients of metallic colours. Thus all glass and glazing that contain lead, will participate in the properties of enamel; and what we shall say of one may be applied to the rest with very trifling differences. Such are the white and transparent glazing of stoneware, and the glazing of porcelain called *soft glazing*.

Flux for soft porcelain colours

Enamel or soft porcelain colours require much less flux than others, because the glass upon which they are applied becomes sufficiently soft to be penetrated by them. This flux may be either glass of lead and pure silex, called *rocaille*, or the same glass mixed with borax. Montamy asserts that glass of lead ought to be banished from among the enamel fluxes; and he employs only borax. He then dilutes his colours in a volatile oil. On the other hand, the painters of the manufactory of Sèvres employ only colours without borax, because they dilute them in gum; and borax does not dilute well in that substance. Brogniart found that both methods were equally good; and it is certain that Montamy was wrong to exclude fluxes of lead, since they are daily employed without any inconvenience, and as they even render the application of colours easier.

We have said that in the baking of these colours, the crust, softened by the fire, suffers itself to be easily penetrated by them. This is the first cause of the change which they experience. By mixing with the crust they become weaker, and the first heat changes a figure which appeared to be finished into a very light sketch.

The two principal causes of the changes which colours on enamel and soft porcelain are susceptible of experiencing do not depend in any manner upon the composition of these colours, but upon the nature of the glass to which they are applied. It follows from what has been said, that paint ing on soft porcelain has need of being several times retouched, and of several heats, in order that it may be carried to the necessary degree of strength. These paintings have always a certain faintness; but they are constantly more brilliant, and they never are attended with the inconvenience of detaching themselves in scales.

Colours applied to hard porcelain, and to glass.

Hard porcelain, according to the division which Brogniart established, is the second sort of excipient of metallic colours. This porcelain, as is well known, has for its base a very white clay called *kaolin*, mixed with a siliceous and calcareous flux, and for its covering feldspar fused without an atom of lead. The same porcelain, which is that of Saxony, is much newer at Sèvres than the soft porcelain. The colours applied to it are of two kinds. The first, destined to represent different objects, are baked in a heat very inferior to that which is necessary for baking porcelain. They are exceedingly numerous and varied. The others, destined to be fused in the same heat as that which bakes porcelain, lay themselves flat, and are much less numerous. The colours of painting are made nearly like those destined for soft porcelain; they only contain more flux. Their flux is composed of glass of lead and borax. When porcelain is exposed to heat in order to bake the colours, the covering of feldspar dilates itself and opens its pores, but does not become soft; and as the colours do not penetrate it, they experience none of those changes which they undergo on soft porcelain. It must however be said that they lose a little of their intensity by acquiring that transparency which is given to them by fusion.

One of the greatest inconveniences of these colours, especially in the manufactory of Sèvres, is the facility with which they scale off when exposed several times in the fire. To remedy this defect without altering the quality of the paste, Brogniart was of opinion that the crust only ought to be softened by introducing into it more siliceous or calcareous flux, according to the nature of the feldspar. This method succeeded, and being employed, the colours might be exposed two or three times to the fire without scaling, if not overcharged with flux, and laid on too thick.

The third sort of excipient of vitrifiable metallic colours is glass without lead. The application of these colours to glass constitutes painting on glass; an art very much practised some centuries ago, and which was supposed to be lost because out of fashion; but it has too direct a dependence on painting in enamel and porcelain to be entirely lost.

The matters and fluxes which enter into the composition of the colours employed on glass are in general the same as those applied to porcelain. Neither of them differ except in their proportions; but there are a great number of enamel or porcelain colours which cannot be applied to glass, where they are deprived of the white ground that serves to give them relief.

Of Colours in particular.

After collecting the general phenomena exhibited by each class of vitrifiable colours, considered in regard to the body on which they are applied, we shall now make known the most interesting particular phenomena exhibited by each principal kind of colours employed upon soft porcelain and glass in a porcelain furnace.

Reds, Purples, and Violets, made from Gold.

Carmine red is obtained by the purple precipitate of cassius. It is mixed with about six parts of its flux; and this mixture is employed directly, without being fused. It is then of a dirty violet, but by baking it acquires a beautiful red carmine colour. It is, however, exceedingly delicate; but a little too much heat and carbonaceous vapours easily spoil it. On this account it is more beautiful when baked with charcoal than with wood.

This colour and the purple, which is very little different, as well as all the shades obtained from it by mixing it with other colours, really change on all porcelain and in every hand. But it is the only one which changes on hard porcelain. Its place may be supplied by a rose-colour from iron which does not change; so that by suppressing the carmine made with gold, and substituting for it the rose oxide of iron here alluded to, a palette may be exhibited, composed of colours none of which changes in a remarkable manner. This rose-coloured oxide of iron has long been known; but it was not employed on enamel, because on that substance it changed too much. As the painters on enamel, however, have become the painters on porcelain, they have preserved their ancient method.

It might be believed that, by first reducing to a vitreous matter the colour called *carmine* already mixed with its flux, it might be made to assume its last tint. But the heat necessary to fuse this vitreous mass destroys the red colour. Besides, it is remarked that, to obtain this colour very beautiful, it must be exposed to the fire as few times as possible. The carmine for soft porcelain is made with fulminating gold slowly decomposed, and muriate of silver; no tin enters into it, which proves that the combination of the oxide of this metal with that of gold is not necessary to the existence of the purple colour. Violet is also made with purple oxide of gold. A greater quantity of lead in the flux is what gives it this colour, which is almost the same crude or baked. These three colours totally disappear when exposed to a great porcelain heat.

Carmine and purple give us in glass only tints of a dirty violet. The violet, on the other hand, produces on glass a very beautiful effect, but it is liable to turn blue. We have not been able to discover the cause of this singular change.

Red, Rose, and Brown Colours, extracted from Iron.

These colours are made from red oxide of iron prepared with nitric acid. The oxides are further calcined by keeping them exposed to the action of heat; but if heated too much, they pass to brown. Their flux is composed of borax, sand, and minium, in small quantity.

These oxides give rose and red colours capable of supplying the place of the same colours made with oxide of gold. When properly employed upon hard porcelain, they do not change at all. We have caused roses to be painted with these colours, and found no difference between the baked flower and that not baked, except what might be expected to result from the brilliancy given to colours by fusion.

These colours may be employed indiscriminately, either previously fused or not fused. In a great heat they in part disappear, or produce a dull brick ground, which is not agreeable. The composition of them is the same both for soft porcelain and for glass. They do not change on the latter; but on soft porcelain they disappear almost entirely on the first exposure to heat, and to make any thing remain they must be employed very deep. This singular effect must be ascribed to the presence of lead in the crust or glazing. We assured ourselves of this by a very simple experiment. We placed this colour on window glass, and having exposed it to a strong baking, it did not change. We covered several parts of it with minium; and on again exposing it to the fire, the colour was totally removed in the places where the red oxide of lead had been applied. By performing this operation on a larger scale in close vessels, a large quantity of oxygen gas was disengaged.

It appears to us that the observation here referred to clearly proves the action of oxidated lead on glass as a destroyer of colour; it is seen that it does not act, as was believed, by burning the combustible bodies, which might tarnish the glass, but by dissolving, discolouring, or volatilizing with it the oxide of iron, which might alter its transparency.

Yellows.

Yellows are colours which require a great deal of care in the fabrication, on account of the lead which they contain, and which, approaching sometimes to the metallic state, produces on them dark spots. The yellows for hard and soft porcelain are the same; they are composed of the oxide of lead, white oxide of antimony, and sand.

Oxide of tin is sometimes mixed with them; and when it is required to have them more lively, and nearer the colour *du souci*, red oxide of iron is added, the too great redness of which is dissipated in the previous fusion to which they are exposed by the action of the lead contained in this yellow. These colours, when once made, never change; they disappear, however, almost entirely when exposed to a porcelain heat.

These yellows cannot be applied to glass, because they are too opaque and dirty. That employed by the old painters on glass has, on the contrary, a beautiful transparency, and is exceedingly brilliant, and of a colour which approaches near to that of gold. The processes which they gave clearly showed that silver formed part of their composition; but, when exactly followed, nothing satisfactory was obtained. M. Miraud found means to make as beautiful paintings on glass as the ancients, by employing muriate of silver, oxide of zinc, white argil, and yellow oxide of iron. These colours were applied on glass merely pounded, and without a flux. The oxide of iron brought the yellow to that colour which it ought to have after baking, and contributed with the argil and oxide of zinc to decompose the muriate of silver without deoxidating the silver. After the baking, there remained a dust which had not penetrated into the glass, and which was easily removed.

This yellow, when employed thicker, gives darker shades, and produces a russet colour.

Blues.

It is well known that blues are obtained from the oxide of cobalt. All chemists are acquainted with the preparation of them. Those of Sèvres, which are justly esteemed for their beauty, are indebted for it solely to the care employed in manufacturing them, and to the quality of the porcelain, which appears more proper for receiving them in proportion to the degree of heat which it can bear.

Respecting the oxide of cobalt, we may remark a fact which is perhaps not known to chemists; namely, its volatility in a violent heat. It is to this property that we must ascribe the bluish tint always assumed by white in the neighbourhood of the blue.

The blue of hard porcelain, destined for what is called the ground of a great heat *(les fonds au grand feu)* is fused with feldspar; that of soft porcelain has for its flux silex, potash, and lead. It is not volatilized like the preceding; but the heat which it experiences is very inferior to that of hard porcelain. These colours, when previously fused, do not change at all in the application. Blues on glass exhibit the same phenomena as those on soft porcelain.

Greens.

The greens employed in painting are made with green oxide of copper, or sometimes with a mixture of yellow or blue. They must be previously fused with their flux, otherwise they will become black; but after this first fusion they no longer change. They cannot stand a strong heat, as it would make them disappear entirely. Green grounds for a strong heat are composed with the oxides of cobalt and nickel, but a brownish green only is obtained.

Bluish greens, called *celestial blues*, which were formerly colours very much in vogue, can be applied only upon soft porcelain; on hard porcelain they consequently become scaly, because potash enters into their composition. These greens cannot be applied on glass, because they give a dirty colour. To obtain a green on glass, it is necessary to put yellow on one side, and blue, more or less pale, on the other. This colour may be also made by a mixture of blue with yellow oxide of iron.

Bistres and Russets.

These are obtained by mixtures, in different proportions, of manganese, brown oxide of copper, and oxide of iron from ombre earth. They are also previously fused with their flux, so that they do not in any manner change on soft porcelain, since lead has not the same action on oxide of manganese as on that of iron. This colour fades very speedily on glass.

Russet grounds in a great heat, known under the name of *tortoise-shell grounds*, are made in the same manner. Their flux is feldspar; and no titanium enters into their composition, though it is so stated in all printed works. Titanium was not known at the manufactory of Sèvres when Brogniart arrived there. He treated this singular metal in various ways, and never obtained any but grounds of a pale dirty yellow, and very variable in tone.

Blacks.

Blacks are the colours the most difficult to be obtained of a very beautiful hue. No metallic oxide alone gives a beautiful black. Manganese is that which approaches nearest to it. Iron gives an opaque, dull, cloudy black, which changes very easily to red; the colour-makers, therefore, to obtain a black which they could not hope for from the best theorist, have united several metallic oxides which separately do not give black, and have obtained a very beautiful colour, which, however, is liable to become scaly and dull. These oxides are those of manganese, the brown oxides of copper, and a little of the oxide of cobalt. The grey is obtained by suppressing the copper, and increasing the dose of the flux.

The manufactory of Sèvres is the only one which has hitherto produced beautiful blacks in a strong heat. This is owing rather to the quality of its paste than to any peculiar processes, since it does not conceal them. It is by darkening the blue by the oxides of manganese and iron that they are able in that manufactory to obtain very brilliant blacks.

Having here made known the principles of the fabrication of each principal colour, it may be readily conceived that by mixing these colours together all the shades possible may be obtained. It is evident also that care in the preparation, choice in the raw materials, and a just proportion of doses, must produce in the result, differences very sensible to an eye accustomed to painting. A mere knowledge of the composition of the colours does not give the talent of executing them well.

Facts relative to colours recapitulated.

From the facts above mentioned, it is therefore seen, 1st, That amongst colours generally employed on hard porcelain one only is susceptible of changing, viz. carmine, and the tints into which it enters; that its place may be supplied by the reds of iron, and that no colour then changes. 2d, That amongst the colours for soft porcelain and enamel, several change in a considerable degree. These are principally the reds of gold and iron, the yellows, the greens, and the browns. They have not been replaced by others, because this kind of painting has been almost abandoned. 3d, That several of the colours on glass change also by acquiring complete transparency. These, in particular, are the yellows and green. 4th, That it is neither by calcining the colours in a higher degree, nor previously fusing them, as supposed by some, that they are prevented from changing, since these means really alter the changing colours, and produce no effect on the rest. The change which several colours experience upon soft porcelain and upon glass does not depend on the nature of their composition, but rather on that of the body upon which they are applied.

It follows, then, that, by suppressing from the colours of hard porcelain the carmine of gold, which is by no means indispensably necessary, we shall have a series of colours which do not change, or, in other words, remain unalterable. So much for the colours employed in this manufacture. X. X.

PORCH, in *Architecture*, a kind of vestibule supported by columns, and much used at the entrance of temples, halls, and other edifices.

A porch, in ancient architecture, was a vestibule, or a disposition of insulated columns usually crowned with a pediment, forming a covert place before the principal door of a temple or court of justice. When a porch had four columns in front, it was called a tetrastyle; when six, a hexastyle; when eight, an octostyle, and so on.

PORCH, in Greek στοα, a public portico in Athens, adorned with the pictures of Polygnotus and other eminent painters. It was in this portico that Zeno the philosopher taught; and hence his followers were called Stoics.

PORCHESTER, a village of the county of Hants and in the hundred of Portsdown. It is on the north side of Portsmouth harbour, and is remarkable for its extensive and ancient castle, in which, during the war, some thousands of French prisoners were confined. The walls inclose a square of four acres. It formerly belonged to the crown, and was settled by Edward IV. on his queen Margaret. It is now private property, and during the war was rented by the government, and converted into a prison. Since the peace, the population has somewhat declined, having been in 1801, 917; in 1811, 818; in 1821, 757; and in 1831, 739.

PORCO, a province of Bolivia in South America, to the west of the city of Potosi. The region is elevated, and the climate is consequently cold, so that although in the valleys the soil is productive, there is a scarcity of grains and fruit. It is properly a pastoral country, and here are reared vast numbers of sheep, and also vicuñas and guanacos, native sheep. The mountain of Porco in this province is celebrated for its silver mines. It was the first worked by the Spaniards after the conquest; and before that epoch it had been the source whence the Incas of Peru obtained their chief supplies of the precious metal. The original mine is still wrought, but, like most others in this quarter, without much vigour. Porco, the capital of the province, is a small town with but few inhabitants. The population of the province is estimated at above one hundred thousand.

PORCU, a town on the sea-coast of Hindustan, situated in the province of Travancore. It is populous, and carries on a considerable trade. The adjacent country is fertile, and produces abundance of rice. The inhabitants consist of Mahommedan, Hindu, and Christian merchants. The Dutch had formerly a factory here for procuring cargoes of pepper. Long. 76. 24. E. Lat. 9. 23. N.

PORDENONE, a city of Austrian Italy, in the province of Milan, and delegation of Belluno. It stands on the river Roncello, and contains 650 houses, with 4230 inhabitants, who are chiefly employed in making linen goods and paper. Lat. 45. 56. 42. Long. 12. 34. 54. E.

PORETSCHIE, a city of the Russian empire, in the province of Smolensko, the capital of a circle of the same name. It is situated on the river Kasplea, which is navigable thus far, but no farther. It is 478 miles from St. Petersburg, and favourably situated as a depôt for the trade between Smolensko and Riga. It contains three churches, 580 houses, and 5900 inhabitants, with large storehouses. Lat. 55. 10. Long. 31. 25. E.

PORISM, in *Geometry*, is a name given by the ancient geometers to two classes of mathematical propositions. Euclid applies this name to propositions, which are involved in others which he is professedly investigating, and which, although they do not form his principal object, are obtained along with it, as is expressed by their name *porismata*, or acquisitions. Such propositions are now called *corollaries*. But he gives the same name, by way of eminence, to a particular class of propositions which he collected in the course of his researches, and selected from amongst many others, on account of their great subserviency to the business of geometrical investigation in general. These propositions were so named by him, either from the way in which he discovered them, that is to say, whilst he was investigating something else, so that they might be considered as *gains* or *acquisitions*, or from their utility as steps in the investigation. In this sense they are *porismata;* for ποριζω (from which, according to Proclus, the term is derived) signifies both to investigate and to acquire by investigation. These propositions formed a collection in three books, which was familiarly known to the ancient geometers by the name of Euclid's *porisms;* and Pappus of Alexandria says, that it was a most ingenious collection of many things conducive to the analysis or solution of the most difficult problems, and which afforded great delight to those who were able to understand and investigate them.

Unfortunately for mathematical science, this valuable collection is now lost, and it still remains a doubtful question in what manner the ancients conducted their researches upon this curious subject. We have, however, reason to believe that their method was both comprehensive and excellent; for their analysis led them to many profound discoveries, and was restricted by the severest logic. The only account we have of this class of geometrical propositions, is in a fragment of Pappus, in which he attempts a general description of them, as a set of mathematical propositions distinguishable in kind from all others; but of this description nothing remains, except a criticism on a definition of the term given by some geometers, namely, "A Porism is that which is deficient in hypothesis from a local theorem," and which he finds fault with, as defining the porisms only by an accidental circumstance. Pappus also gives an account of Euclid's porisms; but the enunciations are so extremely defective, at the same time that they refer to a figure now lost, that Dr. Halley confesses the fragment in question to be beyond his comprehension.

The high encomiums pronounced by Pappus on these propositions have excited the curiosity of the greatest geometers of modern times, who have attempted to discover their nature and the manner of investigating them. Fermat gave a few propositions, which have been published in his *Opera* (Tolosæ, 1679), and Bullialdus, in a tract entitled *Exercitationes Geometricæ Tres* (Paris, 1657), attempted the same thing, but with less success. Albert Girard, at a still earlier period, announced that he had restored the whole of the three books of Euclid, but it does not appear that this part of his works was ever published.[1]

At length Dr. Simson, Professor of Mathematics in the University of Glasgow, was so fortunate as to succeed in restoring the porisms of Euclid. In the preface to his treatise *De Porismatibus*, he gives the following account of his progress and of the obstacles he encountered: "Postquam vero apud Pappum legeram Porismata Euclidis Collectionem fuisse artificiosissimam multarum rerum, quæ spectant ad analysin difficiliorum et generalium problematum, magno desiderio tenebar, aliquid de iis cognoscendi; quare sæpius et multis variisque viis tum Pappi propositionem generalem, mancam et imperfectum, tum primum lib. 1. Porisma, quod, ut dictum fuit, solum ex omnibus in tribus libris integrum adhuc manet, intelligere et restituere conabar; frustra tamen, nihil enim proficiebam. Cumque cogitationes de hac re multum mihi temporis consumpserint, atque tandem molestæ admodum evaserint, firmiter animum induxi haec nunquam in posterum investigare; præsertim cum optimus Geometra Halleius spem omnem de iis intelligendis abjecisset. Unde quoties menti occurrebant, toties eas arcebam. Postea tamen accidit ut improvidum et propositi immemorem invaserint, meque detinuerint donec tandem lux quædam effulserit quae spem mihi faciebat inveniendi saltem Pappi propositionem generalem, quam quidem multa investigatione tandem restitui."

---

[1] In his *Trigonometry*, published at the Hague in 1629, after enumerating the forms of certain rectilinear figures, Girard adds, "Le tout, quand il n'y a que deux lignes qui passent par un point, comme jadis estoyent les Porismes d'Euclid, qui sont perdus, lesquelles J'espère de mettre bientot en lumière, les ayant restituez, il y a quelques années en ça." A similar announcement is also made by him in his edition of the works of Stevinus (Lugduni. Batav. 1634. p. 459.) Having mentioned that Euclid rarely employs a compound ratio, he adds, "Mais il est à estimer qu'il en a plus escrit en ses trois livres de Porismes qui sont perdus, lesquelles, Dieu aidant, J'espère de mettre en lumière, les ayant inventez de nouveau." (See the preface to Simson's *Tractatus de Porismatibus*, in his *Opera Reliqua.*)

Dr. Simson's *Restoration* has every appearance of being just. All the lemmas which Pappus has given for the better understanding of Euclid's propositions are equally applicable to those of Dr. Simson, which are found to differ from local theorems precisely as Pappus affirms those of Euclid to have done. They require a particular mode of analysis, and are of immense service in geometrical investiga tion.

Whilst Dr. Simson was employed in this inquiry, he carried on a correspondence upon the subject with the late Dr. Matthew Stewart, Professor of Mathematics in the University of Edinburgh; who, besides entering into Dr. Simson's views, and communicating to him many curious porisms, pursued the same subject in a new and very different direction. He published the result of his inquiries in 1746, under the title of *General Theorems*, not wishing to give them any other name, lest he might appear to anticipate the labours of his friend and former preceptor. The greater part of the propositions contained in that work are porisms, but without demonstration; and those who wish to investigate one of the most curious subjects in geometry, will there find abundance of materials, and an ample field for discussion.

Dr. Simson defines a porism to be "a proposition, in which it is proposed to demonstrate, that one or more things are given, between which, and every one of innumerable other things not given, but assumed according to a given law, a certain relation, described in the proposition, is to be shewn to take place."

This definition is somewhat obscure, but will be plainer if expressed thus: "A porism is a proposition affirming the possibility of finding such conditions as will render a certain problem indeterminate, or capable of innumerable solutions." This definition agrees with Pappus's idea of these propositions, as far at least as they can be understood from the fragment already mentioned; for the propositions here defined, like those which he describes, are, strictly speaking, neither theorems nor problems, but of an intermediate nature between both. They neither simply enunciate a truth to be demonstrated, nor propose a question to be resolved, but are affirmations of a truth in which the determination of an unknown quantity is involved. In as far, therefore, as they assert that a certain problem may become indeterminate, they are of the nature of theorems; and, in as far as they seek to discover the condition by which that is brought about, they are of the nature of problems.

In order to give our readers a clear idea of the subject of porisms, we shall consider them in the way in which it is probable they occurred to the ancient geometers in the course of their researches. This will at the same time shew the nature of the analysis peculiar to them, and their great use in the solution of problems.

It appears to be certain, that it has been the solution of problems which, in all states of the mathematical sciences, has led to the discovery of geometrical truths. The first mathematical inquiries, in particular, must have occurred in the form of questions, where something was given, and something required to be done; and by the reasoning necessary to answer these questions, or to discover the relation between the things given and those to be found, many truths were suggested, which came afterwards to be the subject of separate demonstrations. The number of these was the greater, because the ancient geometers always undertook the solution of problems, with a scrupulous and minute attention, insomuch that they would scarcely suffer any of the collateral truths to escape their observation.

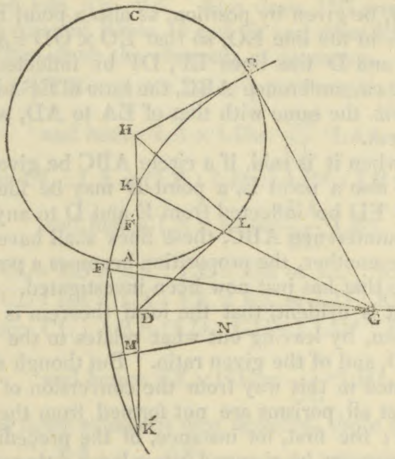
Now, as this cautious manner of proceeding was not better calculated to avoid error than to lay hold of every collateral truth connected with the main object of inquiry, these geometers soon perceived, that there were many problems which in certain cases would admit of no solution whatever, in consequence of a particular relation existing amongst the quantities which were given. Such problems were said to become impossible; and it was soon perceived, that this always happened when one of the conditions of the problem was inconsistent with the rest. Thus, when it was required to divide a line, so that the rectangle contained by its segments might be equal to a given space, it was found that this was possible only when the given space was less than the square of half the line; for when it was otherwise, the two conditions defining, the one the magnitude of the line, and the other the rectangle of its segments, were inconsistent with each other. Such cases would occur in the solution of the most simple problems; but if they were more complicated, it must have been remarked, that the constructions would sometimes fail, for a reason directly contrary to that just now assigned. Cases would occur, where the lines, which by their intersection were to determine the thing sought, instead of intersecting each other as they did commonly, or of not meeting at all, as in the above mentioned case of impossibility, would coincide with one another entirely, and of course leave the problem unresolved. It would appear to geometers upon a little reflection, that since, in the case of determinate problems, the thing required was determined by the intersection of the two lines already mentioned, that is, by the points common to both; so in the case of their coincidence, as all their parts were in common, every one of these points must give a solution, or, in other words, the solutions must be indefinite in number.

Upon inquiry, it would be found that this proceeded from some condition of the problem having been involved in another, so that, in fact, the two formed but one, and thus there was not a sufficient number of independent conditions to limit the problem to a single or to any determinate number of solutions. It would soon be perceived, that these cases formed very curious propositions of an intermediate nature between problems and theorems; and that they admitted of being enunciated in a manner peculiarly elegant and concise. It was to such propositions that the ancients gave the name of *porisms*.

This deduction requires to be illustrated by an example. Suppose, therefore, that it were required to resolve the following problem. A circle ABC, (fig. 1), a straight line DE, and a point F, being given in position, to find a point G in the straight line DE such, that GF, the line drawn from it to the given point, shall be equal to GB, the line drawn from it touching the given circle.

Suppose G to be found, and GB to be drawn touching the given circle ABC in B, let H be its centre, join HB, and let HD be perpendicular to DE. From D draw DL,

Fig. 1.



touching the circle ABC in L, and join HL; also from the centre G, with the distance GB or GF, describe the circle BKF, meeting HD in the points K and K′. It is evident that HD and DL are given in position and magnitude: also because GB touches the circle ABC, HBG is a right angle; and since G is the centre of the circle BKF, HB touches that circle, and consequently HB^2 or $HL^2=KH\times HK'$; but because KK′ is bisected in D, $KH\times HK'+DK^2=DH^2$, therefore $HL^2+DK^2=DH^2$. But $HL^2+LD^2=DH^2$, therefore $DK^2=DL^2$ and $DK=DL$. But DL is given in magnitude, and consequently K is a given point. For the same reason K′ is a given point, therefore the point F being given in position, the circle KFK′ is given in position. The point G, which is its centre, is therefore given in position, which was to be found. Hence this construction:

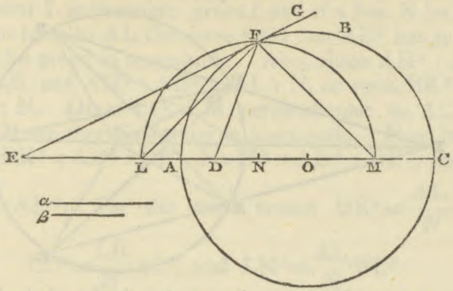
Having drawn HD perpendicular to DE, and DL touching the circle ABC, make DK and DK′ each equal to DL, and find G the centre of the circle described through the points K′FK; that is, let FK′ be joined and bisected at right angles by MN, which meets DE in G, G will be the point required; or it will be such a point, that if GB be drawn touching the circle ABC, and GF to the given point, GB is equal to GF.

The synthetical demonstration is easily derived from the preceding analysis; but it must be remarked, that in some cases this construction fails. For, first, if F fall anywhere in DH, as at F′, the line MN becomes parallel to DE, and the point G is nowhere to be found; or, in other words, it is at an infinite distance from D. This is true in general; but if the given point F coincide with K, then MN evidently coincides with DE; so that, agreeable to a remark already made, every point of the line DE may be taken for G, and will satisfy the conditions of the problem; that is to say, GB will be equal to GK, wherever the point G is taken in the line DE: the same is true if F coincide with K′. Thus we have an instance of a problem, and that too a very simple one, which, in general, admits but of one solution; but which, in one particular case, when a certain relation takes place among the things given, becomes indefinite, and admits of innumerable solutions. The proposition which results from this case of the problem is a porism, and may be thus enunciated:

"A circle ABC being given by position, and also a straight line DE, which does not cut the circle, a point K may be found, such, that if G be any point whatever in DE, the straight line drawn from G to the point K shall be equal to the straight line drawn from G touching the given circle ABC."

The problem which follows, appears to have led to the discovery of many porisms.

Fig. 2.

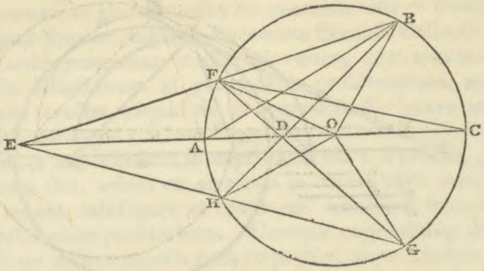


A circle ABC (fig. 2), and two points D, E, in a diameter of it being given, to find a point F in the circumference of the given circle, from which, if straight lines be drawn to the given points E, D, these straight lines shall have to one another the given ratio of α to β, which is supposed to be that of a greater to a less. Suppose the problem resolved, and that F is found, so that FE has to FD the given ratio of α to β; produce EF towards G, bisect the angle EFD by FL, and DFG by FM: therefore EL : LD : : EF : FD, that is in a given ratio, and since ED is given, each of the segments EL, LD, is given, and the point L is also given; again, because DFG is bisected by FM, EM : MD : : EF : FD, that is, in a given ratio, and therefore M is given. Since DFL is half of DFE, and DFM half of DFG, therefore LFM is half of (DFE+DFB), that is, the half of two right angles, therefore LFM is a right angle; and since the points L, M, are given, the point F is in the circumference of a circle described upon LM as a diameter, and therefore given in position. Now the point F is also in the circumference of the given circle ABC, therefore it is in the intersection of the two given circumferences, and therefore is found. Hence this construction: Divide ED in L, so that EL may be to LD in the given ratio of α to β, and produce ED also to M, so that EM may be to MD in the same given ratio of α to β; bisect LM in N, and from the centre N with the distance NL, describe the semicircle LFM; and the point F, in which it intersects the circle ABC, is the point required.

The synthetical demonstration is easily derived from the preceding analysis. It must, however, be remarked, that the construction fails when the circle LFM falls either wholly within or wholly without the circle ABC, so that the circumferences do not intersect; and in these cases the problem cannot be solved. It is also obvious that the construction will fail in another case, viz. when the two circumferences LFM, ABC, entirely coincide. In this case, it is farther evident, that every point in the circumference ABC will answer the conditions of the problem, which is therefore capable of numberless solutions, and may, as in the former instance, be converted into a porism. We are now to inquire, therefore, in what circumstances the point L will coincide with A, and also the point M with C, and of consequence the circumference LFM with ABC. If we suppose that they coincide, EA : AD : : α : β : : EC : CD, and EA : EC : : AD : CD, or by conversion, EA : AC : : AD : CD—AD : : AD : 2DO, O being the centre of the circle ABC; therefore, also, EA : AO : : AD : DO, and by compositition, EO : AO : : AO : DO, therefore $EO\times OD=AO^2$. Hence, if the given points E and D (fig. 3), be so situated that $EO\times OD=AO^2$, and at the same time α : β : : EA : AD : : EC : CD, the problem admits of numberless solutions; and if either of the points D or E be given, the other point, and also the ratio which will render the problem indeterminate, may be found. Hence we have this porism:

"A circle ABC, and also a point D being given, another point E may be found, such that the two lines inflected from these points to any point in the circumference ABC,

Fig. 3.



shall have to each other a given ratio, which ratio is also to be found." Hence also we have an example of the derivation of porisms from one another, for the circle ABC, and the points D and E remaining as before, if, through D we draw any line whatever HDB, meeting the circle in B and H; and if the lines EB, EH, be also drawn, these lines will cut off equal circumferences BF, HG. Let FC be drawn, and it is plain from the foregoing analysis, that the angles DFC, CFB, are equal; therefore if OG, OB, be drawn, the angles BOC, COG, are also equal; and consequently the angles DOB, DOG. In the same manner, by joining AB, the angle DBE being bisected by BA, it is evident that the angle AOF is equal to AOH, and therefore the angle FOB to HOG; hence the arch FB is equal to the arch HG. It is evident that if the circle ABC, and either of the points DE were given, the other point might be found. Therefore we have this porism, which appears to have been the last but one of the third book of Euclid's *Porisms*. "A point being given, either within or without a circle given by position, if there be drawn, anyhow through that point, a line cutting the circle in two points; another point may be found, such, that if two lines be drawn from it to the points in which the line already drawn cuts the circle, these two lines will cut off from the circle equal circumferences."

The proposition from which we have deduced these two porisms, also affords an illustration of the remark, that the conditions of a problem are involved in one another in the porismatic or indefinite case; for here several independent conditions are laid down, by the help of which the problem is to be resolved. Two points D and E are given, from which two lines are to be inflected, and a circumference ABC, in which these lines are to meet, as also a ratio which these lines are to have to each other. Now these conditions are all independent of one another, so that any one may be changed without any change whatever in the rest. This is true in general; but yet in one case, viz. when the points are so related to another, that the rectangle under their distances from the centre is equal to the square of the radius of the circle, it follows, from the preceding analysis, that the ratio of the inflected lines is no longer a matter of choice, but a necessary consequenec of this disposition of the points.

From what has been already said, we may trace the imperfect definition of a porism which Pappus ascribes to the later geometers, viz. that it differs from a local theorem, by wanting the hypothesis assumed in that theorem. Now, to understand this, it must be observed, that if we take one of the propositions called *loci*, and make the construction of the figure a part of the hypothesis, we get what was called by the ancient geometers, a *local theorem*. If, again, in the enunciation of the theorem, that part of the hypothesis which contains the construction be suppressed, the proposition thence arising will be a porism, for it will enunciate a truth, and will require to the full understanding and investigation of that truth, that something should be found, viz. the circumstances in the construction supposed to be omitted.

Thus, when we say, if from two given points, E, D, two straight lines EF, FD, are inflected to a third point F, so as to be to one another in a given ratio, the point F is in the circumference of a given circle, we have a locus. But when conversely, it is said, if a circle ABC, of which the centre is O, be given by position, as also a point E; and if D be taken in the line EO, so that $EO \times OD = AO^2$, and if from E and D the lines EF, DF be inflected to any point of the circumference ABC, the ratio of EF to DF will be given, viz. the same with that of EA to AD, we have a local theorem.

Lastly, when it is said, if a circle ABC be given by position, and also a point E, a point D may be found, such that if EF, FD be inflected from E and D to any point F in the circumference ABC, these lines shall have a given ratio to one another, the proposition becomes a porism, and is the same that has just now been investigated.

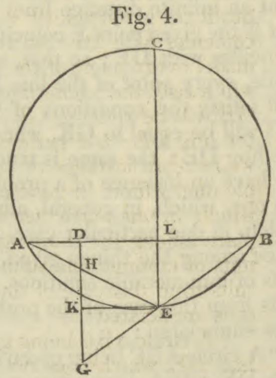
Hence it is evident, that the local theorem is changed into a porism, by leaving out what relates to the determination of D, and of the given ratio. But though all propositions formed in this way from the conversion of loci, are porisms, yet all porisms are not formed from the conversion of loci; the first, for instance, of the preceding, cannot, by conversion, be changed into a locus; therefore Fermat's idea of porisms, founded upon this circumstance, could not fail to be imperfect.

If the idea which we have given of these propositions be just, it follows, that they are to be discovered by considering those cases in which the construction of a problem fails, in consequence of the lines which by their intersection, or the points which by their position, were to determine the problem required, happening to coincide with one another. A porism may therefore be deduced from the problem to which it belongs, just as propositions concerning the *maxima* and *minima* of quantities are deduced from the problems of which they form limitations; and such is the most natural and obvious analysis of which this class of propositions admits.

Another general remark which may be made on the analysis of porisms is, that it often happens that the magnitudes required may all, or a part of them, be found by considering the extreme cases; but for the discovery of the relation between them, and the indefinite magnitudes, we must have recourse to the hypothesis of the porism in its most general or indefinite form; and must endeavour so to conduct the reasoning, that the indefinite magnitudes may at length totally disappear, and leave a proposition asserting the relation between determinate magnitudes only.

For this purpose accordingly Dr. Simson frequently employs two statements of the general hypothesis, which he compares together. This double statement, however, cannot be made without rendering the investigation long and complicated; nor is it even necessary, for it may be avoided by having recourse to simpler *porisms*, or to *loci*, or to propositions of the *data*. The porism which follows, is given as an example where this is done with some difficulty, but with considerable advantage, both with regard to the simplicity and shortness of the demonstration. It will be proper to premise the following lemma.

Fig. 4.



Let AB (fig. 4.) be a straight line, and D, L any two points in it, one of which D is between A and B; also let CL be any straight line. Then shall

$$\frac{LB}{CL}\cdot AD^2+\frac{LA}{CL}\cdot BD^2=\frac{LB}{CL}\cdot AL^2+\frac{LA}{CL}\cdot BL^2+\frac{AB}{CL}DL^2.$$

For place CL perpendicular to AB, and through the points

A, C, B describe a circle, and let CL meet the circle again in E, and join AE, BE. Also draw DG parallel to CE, meeting AE and BE in H and G, and draw EK parallel to AB. Then, from the elements of geometry,

$$\mathrm{CL : LB :: (LA : LE ::)\ LA^2 : LA \times LE},$$

$$\text{and hence } \mathrm{LA \times LE} = \frac{\mathrm{LB}}{\mathrm{CL}} \cdot \mathrm{LA^2}.$$

$$\text{Also } \mathrm{CL : LA :: (LB : LE ::)\ LB^2 : LB \times LE},$$

$$\text{and hence } \mathrm{LB \times LE} = \frac{\mathrm{LA}}{\mathrm{CL}} \cdot \mathrm{LB^2}.$$

$$\text{Now } \mathrm{CL : LB :: LA : LE :: EK} \text{ or } \mathrm{LD : KH},$$

$$\text{and } \mathrm{CL : LA :: LA : LE :: EK} \text{ or } \mathrm{LD : KG},$$

$$\text{therefore, } \mathrm{CL : AB :: (LD : GH ::)\ LD^2 : EK \times GH},$$

$$\text{and hence } \mathrm{EK \times GH} = \frac{\mathrm{AB}}{\mathrm{CL}} \cdot \mathrm{LD^2}.$$

From the three equations now deduced, there results

$$\frac{\mathrm{LB}}{\mathrm{LC}}.\mathrm{LA^2} + \frac{\mathrm{LA}}{\mathrm{LC}}.\mathrm{LB^2} + \frac{\mathrm{AB}}{\mathrm{CL}}.\mathrm{LD^2} = \mathrm{AB \times LE + EK \times GH}.$$

Again, because

$$\mathrm{CL : LA :: (LB : LE :: DB : DG ::)\ DB^2 : DB \times DG},$$

therefore $\mathrm{DB \times DG} = \frac{\mathrm{LA}}{\mathrm{CL}} \cdot \mathrm{DB^2}$. And because

$$\mathrm{CL : LB :: (LA : LE :: DA : DH ::)\ DA^2 : DA \times DH},$$

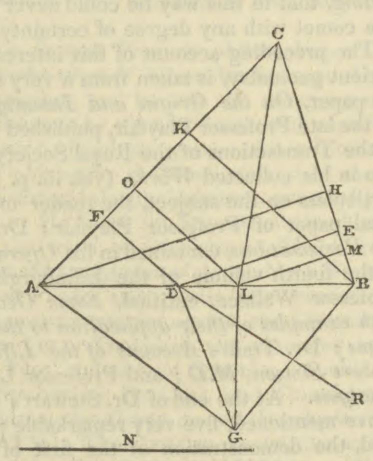
therefore $\mathrm{DA \times DH} = \frac{\mathrm{LB}}{\mathrm{CL}}.\mathrm{DA^2}$. From the result of these two last propositions we have

$$\frac{\mathrm{LB}}{\mathrm{CL}} \cdot \mathrm{DA^2} + \frac{\mathrm{LA}}{\mathrm{CL}} \mathrm{DB^2} = \mathrm{DA \times DH + DB \times DG};$$

But $\mathrm{DA \times DH}$=*twice trian.* ADH, and $\mathrm{DB \times DG}$=*twice trian.* BDG, and therefore $\mathrm{DA \times DH + DB \times DG} = 2$ (*trian.* ADH + *trian.* BDG) = 2 (*trian.* AEB + *trian.* HEG) $= \mathrm{AB \times LE + EK \times HG}$. Now it has been proved, that $\mathrm{DA \times DH + DB \times DG} = \frac{\mathrm{LB}}{\mathrm{CL}} \cdot \mathrm{DA^2} + \frac{\mathrm{LA}}{\mathrm{CL}}.\mathrm{BD^2}$, and that $\mathrm{AB \times LE + EK \times HG} = \frac{\mathrm{LB}}{\mathrm{CL}} \cdot \mathrm{LA^2} + \frac{\mathrm{LA}}{\mathrm{CL}} \cdot \mathrm{LB^2} + \frac{\mathrm{AB}}{\mathrm{CL}} \cdot \mathrm{LD^2}$, therefore $\frac{\mathrm{LB}}{\mathrm{CL}} \cdot \mathrm{AD^2} + \frac{\mathrm{LA}}{\mathrm{CL}} \mathrm{BD^2} = \frac{\mathrm{LB}}{\mathrm{CL}} \cdot \mathrm{AL^2} + \frac{\mathrm{LA}}{\mathrm{CL}} \cdot \mathrm{BL^2} + \frac{\mathrm{AB}}{\mathrm{CL}} \cdot \mathrm{DL^2}$, as was to be demonstrated.

Porism. Let there be three straight lines AB, AC, CB given in position; (fig. 5) and from any point whatever in one of them, as D, let perpendiculars be drawn to the other two, as DF, DE, a point G may be found, such, that if GD be drawn from it to the point D, the square of that line shall have a given ratio to the sum of the squares of the perpendiculars DF and DE, which ratio is to be found.

Fig. 5.



Draw AH, BK perpendicular to BC and AC; and in AB take L, so that $\mathrm{AL : LB :: AH^2 : BK^2 :: AC^2 : CB^2}$. The point L is therefore given; and if a line N be taken, so as to have to AL the same ratio that $\mathrm{AB^2}$ has to $\mathrm{AH^2}$, N will be given in magnitude. Also, since $\mathrm{AH^2 : BK^2 :: AL : LB}$, and $\mathrm{AH^2 : AB^2 :: AL : N}$, *ex equo*, $\mathrm{BK^2 : AB^2 :: LB : N}$. Draw LO, LM perpendicular to AC, CB LO, LM are therefore given in magnitude. Now, because $\mathrm{AB^2 : BK^2 :: AD^2 : DF^2}$, $\mathrm{N : LB :: AD^2 : DF^2}$, and $\mathrm{DF^2} = \frac{\mathrm{LB}}{\mathrm{N}} \cdot \mathrm{AD^2}$. For the same reason $\mathrm{DE^2} = \frac{\mathrm{AL}}{\mathrm{N}} \cdot \mathrm{BD^2}$.

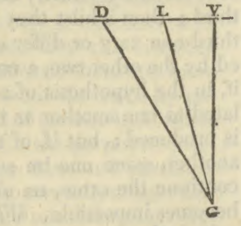
$$\mathrm{LO^2} = \frac{\mathrm{LB}}{\mathrm{N}} \cdot \mathrm{AL^2}, \text{ and } \mathrm{LM^2} = \frac{\mathrm{AL}}{\mathrm{N}} \cdot \mathrm{BL^2}.$$

But, by the preceding lemma, $\frac{\mathrm{LB}}{\mathrm{N}} \cdot \mathrm{AD^2} + \frac{\mathrm{AL}}{\mathrm{N}} \cdot \mathrm{BD^2} = \frac{\mathrm{LB}}{\mathrm{N}} \cdot \mathrm{AL^2} + \frac{\mathrm{AL}}{\mathrm{N}} \cdot \mathrm{BL^2} + \frac{\mathrm{AB}}{\mathrm{N}} \cdot \mathrm{DL^2}$; that is, $\mathrm{DE^2 + DF^2} = \mathrm{LO^2 + LM^2} + \frac{\mathrm{AB}}{\mathrm{N}} \cdot \mathrm{DL^2}$. Join LG, then by hypothesis $\mathrm{LO^2 + LM^2}$ has to $\mathrm{LG^2}$, the same ratio as $\mathrm{DF^2 + DE^2}$ has to $\mathrm{DG^2}$; let it be that of R to N, then $\mathrm{LO^2 + LM^2} = \frac{\mathrm{R}}{\mathrm{N}}.\mathrm{LG^2}$; and therefore $\mathrm{DE^2 + DF^2} = \frac{\mathrm{R}}{\mathrm{N}}.\mathrm{LG^2} + \frac{\mathrm{AB}}{\mathrm{N}}.\mathrm{DL^2}$; but $\mathrm{DE^2 + DF^2} = \frac{\mathrm{R}}{\mathrm{N}}.\mathrm{DG^2}$; therefore, $\frac{\mathrm{R}}{\mathrm{N}}.\mathrm{LG^2} + \frac{\mathrm{BA}}{\mathrm{N}}.\mathrm{DL^2} = \frac{\mathrm{R}}{\mathrm{N}}.\mathrm{DG^2}$, and $\frac{\mathrm{AB}}{\mathrm{N}}.\mathrm{DL^2} = \frac{\mathrm{R}}{\mathrm{N}}(\mathrm{DG^2 - LG^2})$; therefore $\mathrm{DG^2 - LG^2}$ has to $\mathrm{DL^2}$ a constant ratio, viz. that of AB to R. The angle DLG is therefore a right angle, and the ratio of AB to R that of equality, otherwise LD would be given in magnitude, contrary to the supposition. LG is therefore given in position: and since $\mathrm{R : N :: AB : N :: LO^2 + LM^2 : LG^2}$; therefore the square of LG, and consequently LG, is given in magnitude. The point G is therefore given, and also the ratio of $\mathrm{DE^2 = DF^2}$ to $\mathrm{DG^2}$, which is the same with that of AB to N.

The construction easily follows from the analysis, but it may be rendered more simple; for since $\mathrm{AH^2 : AB^2 :: AL : N}$, and $\mathrm{BK^2 : AB^2 :: BL : N}$; therefore $\mathrm{AH^2 + BK^2 : AB^2 :: AB : N}$. Likewise, if AG, BG, be joined, $\mathrm{AB : N :: AH^2 : AG^2}$, and $\mathrm{AB : N :: BK^2 : BG^2}$; wherefore, $\mathrm{AB : N :: AH^2 + BK^2 : AG^2 + BG^2}$, but it was proved that $\mathrm{AB : N :: AH^2 + BK^2 : AB^2}$, therefore $\mathrm{AG^2 + BG^2 = AB^2}$; therefore the angle AGB is a right angle, and $\mathrm{AL : LG :: LG : LB}$. If therefore AB be divided in L, so that $\mathrm{AL : LB :: AH^2 : BK^2}$; and if LG, a mean proportional between AL and LB, be placed perpendicular to AB, G will be the point required.

The step in the analysis, by which a second introduction of the general hypothesis is avoided, is that in which the angle GLD is concluded to be a right angle; which follows from $\mathrm{DG^2 - GL^2}$ having a given ratio to $\mathrm{LD^2}$, at the same time that LD is of no determinate magnitude. For, if possible, let GLD be obtuse, (fig. 6,) and let the perpendicular from G to AB meet in V, therefore V is given: and since $\mathrm{GD^2 - LG^2} = \mathrm{LD^2 \times 2DL \times LV}$; therefore, by the supposition, $\mathrm{LD^2 + 2\,DL \times LV}$ must have a given ratio to $\mathrm{LD^2}$; therefore the ratio of $\mathrm{LD^2}$ to $\mathrm{DL \times VL}$, that is, of LD to VL, is given, so that VL being given in magnitude, LD is also given. But this is contrary to the supposition; for LD is indefinite by hypothesis, and therefore GLD cannot be obtuse,

Fig. 6.



nor any other than a right angle. The conclusion that is here drawn immediately from the indetermination of LD would be deduced, according to Dr. Simson's method, by assuming another point D′ any how, and from the supposition that $GD'^2-GL^2 : LD'^2 :: GD^2-GL^2 : LD^2$, it would easily appear that GLD must be a right angle, and the ratio that of equality.

These porisms facilitate the solution of the general problems from which they are derived. For example, let three straight lines AB, AC, BC, (fig. 5), be given in position, and also a point R, to find a point D in one of the given lines, so that DE and DF being drawn perpendicular to BC, AC, and DR, joined; DE^2+DF^2 may have to DR^2 a given ratio. It is plain, that having found G, the problem would be nothing more than to find D, such that the ratio of GD^2 to DR^2, and therefore that of GD to DR, might be given, from which it would follow, that the point D is in the circumference of a given circle, as is well known to geometers.

The same porism also assists in the solution of another problem. For if it were required to find D such that DE^2+DF^2 might be a given space; having found G, DG^2 would have to DE^2+DF^2 a given ratio, and DG would therefore be given; whence the solution is obvious.

The connection of this porism with the impossible case of the problem is evident; the point L being that from which, if perpendiculars be drawn to AC and CB, the sum of their squares is the least possible. For since $DF^2+DE^2 : DG^2 :: LO^2+LM^2 : LG^2$; and since LG is less than DG, LO^2+LM^2 must be less than DF^2+DE^2.

It is evident from what has now appeared, that in some instances at least there is a close connection between these propositions and the *maxima* or *minima*, and of consequence the impossible cases of problems. The nature of this connection requires to be farther investigated, and is the more interesting because the transition from the indefinite to the impossible case seems to be made with wonderful rapidity. Thus in the first proposition, though there be not properly speaking an impossible case, but only one where the point to be found goes off *in infinitum*, it may be remarked, that if the given point F (fig. 1), be anywhere out of the line HD, the problem of drawing GB equal to GF is always possible, and admits of just one solution; but if F be in DH, the problem admits of no solution at all, the point being then at an infinite distance, and therefore impossible to be assigned. There is, however, this exception, that if the given point be at K in this same line, DH is determined by making DK equal to DL. Then every point in the line DE gives a solution, and may be taken for the point G. Here therefore the case of numberless solutions, and of no solution at all, are as it were *conterminal*, and so close to one another, that if the given point be at K the problem is indefinite; but if it remove ever so little from K, remaining at the same time in the line DH, the problem cannot be resolved. This affinity might have been determined *a priori;* for, as we have seen, it is a general principle, that a problem is converted into a porism when one or when two of the conditions of it necessarily involve in them some one of the rest. Suppose, then, that two of the conditions are exactly in that state which determines the third; then whilst they remain fixed or given, should that third one vary or differ ever so little from the state required by the other two, a contradiction will ensue. Therefore if, in the hypothesis of a problem, the conditions be so related to one another as to render it indeterminate, a porism is produced; but if, of the conditions thus related to one another, some one be supposed to vary, whilst the others continue the same, an absurdity follows, and the problem becomes impossible. *Wherever, therefore, any problem admits both of an indeterminate and an impossible case, it is certain, that these cases are nearly related to one another, and that some of the conditions by which they are produced are common to both.*

It is supposed above, that *two* of the conditions of a problem involve in them a third; and wherever that happens, the conclusion which has been deduced will invariably take place. But a porism may in some cases be so simple as to arise from the mere coincidence of *one* condition with another, though in no case whatever can any inconsistency take place between them. There are, however, comparatively few porisms so simple in their origin, or that arise from problems where the conditions are but little complicated; for it usually happens that a problem which can become indefinite may also become impossible; and if so, the connection already explained never fails to take place.

Another species of impossibility may frequently arise from the porismatic case of a problem which will affect in some measure the application of geometry to astronomy, or any of the sciences depending upon experiment or observation. For when a problem is to be resolved by means of data furnished by experiment or observation, the first thing to be considered is, whether the data so obtained be sufficient for determining the thing sought; and in this a very erroneous judgment may be formed, if we rest satisfied with a general view of the subject. For though the problem may in general be resolved from the data with which we are provided, yet these data may be so related to one another in the case under consideration, that the problem will become indeterminate, and instead of one solution will admit of an indefinite number. This we have already found to be the case in the foregoing propositions. Such cases may not indeed occur in any of the practical applications of geometry; but there is one of the same kind which has actually occurred in astronomy. Sir Isaac Newton, in his *Principia*, has considered a small part of the orbit of a comet as a straight line described with an uniform motion. From this hypothesis, by means of four observations made at proper intervals of time, the determination of the path of the comet is reduced to this geometrical problem. Four straight lines being in position, it is required to draw a fifth line across them, so as to be cut by them into three parts, having given ratios to one another. Now this problem had been constructed by Dr. Wallis and Sir Cristopher Wren, and also in three different ways by Sir Isaac himself in different parts of his works; yet none of these geometers observed that there was a particular situation of the lines in which the problem admitted of innumerable solutions; and this happens to be the very case in which the problem is applicable to the determination of the comet's path, as was first discovered by Boscovich, who was led to it by finding, that in this way he could never determine the path of a comet with any degree of certainty.

The preceding account of this interesting branch of the ancient geometry, is taken from a very elegant and elaborate paper, *On the Origin and Investigation of Porisms*, by the late Professor Playfair, published in the third volume of the Transactions of the Royal Society of Edinburgh, and also in his collected *Works*, (vol. iii. p. 178.) For further particulars on the subject, the reader may consult the original paper of Professor Playfair; Dr. Simson's treatise, *De Porismatibus*, contained in his *Opera Reliqua;* a paper in the fourth volume of the Edinburgh Transactions, by Professor Wallace, entitled, *Some Geometrical Porisms, with examples of their application to the Solution of Problems;* Dr. Traill's *Account of the Life and Writings of Robert Simson, M.D;* and Professor Leslie's *Geometrical Analysis*. At the end of Dr. Stewart's *General Theorems*, above mentioned, five very remarkable porisms are enunciated, the demonstration of the first of which is given in Leybourn's *Mathematical Repository*, (vol. i.) and of the remaining four in the fifth volume of the same work published in 1830. The algebraic analysis may frequently be applied with great advantage in the investigation of porisms, but this manner of treating the subject does not come within the scope of the present article.

PORK, the flesh of swine killed for the purposes of food. The hog is the only domestic animal that we know which is of no use to man when alive, and therefore seems properly designed for food. Besides being loathsome and ugly to every eye, it is killed without reluctance. The Pythagoreans, whether to preserve health, or on account of compassion, generally forbade the use of animal food; and yet it is alleged that Pythagoras reserved the use of hog's flesh for himself. The Jews, the Egyptians, and other inhabitants of warm countries, and all the Mahomedans, reject the use of pork. It is difficult to discover a satisfactory reason for this, or for the precept given to the Jews respecting it, though unquestionably some good one might be assigned. The Greeks greatly commended this food; and Galen everywhere speaks in its praise. The Romans considered it as one of their delicacies; and if some of the inhabitants of the northern climates have taken an aversion to it, that probably arose from their country not being fitted to rear it. Pork is of a very tender structure, increased perhaps from a peculiarity in its economy, namely, taking on fat more readily than any other animal. Pork is a white meat even in its adult state, and then gives out a jelly in great quantity.

PORLOCK, a small market town of Somersetshire, in the hundred of Carhampton, 170 miles from London. It stands at the foot of a lofty range of mountains, on a beautiful bay of its own name, on the Bristol channel. The inhabitants were, in 1801, 600; in 1811, 633; in 1821, 769; and in 1831, 830.

PORO-ISLE, commonly called Porto-Sipora or the island of Good Fortune. It contains four villages, in each of which there are about a thousand inhabitants. It is thirty-three miles in length, by eight in average breadth, and is almost wholly covered with wood. It is situated on the south-western coast of the Poggy Islands, and is inhabited by a race of people similar both in manners and language. Long. 99. 15. E. Lat. 2. 12. S.

PORONNISHIR, one of the Kurile islands in the North Pacific Ocean, about 44 miles in length and 12 in breadth. It is unequal in its surface; the northern part being mountainous, but the north-west less so, though it is still diversified by hills and valleys, one chain of hills rising to a great height, and being never wholly free from snow. It contains abundance of minerals, but is destitute of timber. Wolves and red foxes are found here in plenty; and there is a considerable bay at the north-eastern extremity. The most northern point of the island is Cape Wasitieff, in long. 156. 14. E. Lat. 51. 38. N.

PORPHYRIUS, a famous Platonic philosopher, was born at Tyre in 233, in the reign of Alexander Severus. He was the disciple of Longinus, and became the ornament of his school at Athens, whence he went to Rome, and attended Plotinus, with whom he lived six years. After Plotinus's death he taught philosophy at Rome with great success, and became well skilled in polite literature, geography, astronomy, and music. He lived till the end of the third century, and died in the reign of Diocletian. There are still extant his book on the Categories of Aristotle; a Treatise on Abstinence from Flesh; and several other pieces in Greek. He also composed a treatise against the Christian religion, which is now lost. That work was answered by Methodius bishop of Tyre, and also by Eusebius, Apollinarius, St. Augustin, St. Jerome, St. Cyril, and Theodoret. The Emperor Theodosius the Great caused Porphyrius's book to be burned in 338. Those of his works that are still extant were printed at Cambridge in 1655, 8vo, with a Latin version.

"Porphyrius," says Dr. Enfield, "was, it must be owned, a writer of deep erudition; and had his judgment and integrity been equal to his learning, he would have deserved a distinguished place among the ancients. But neither the splendour of his diction, nor the variety of his reading, can atone for the credulity or the dishonesty which filled the narrative part of his works with so many extravagant tales, or interest the judicious reader in the abstruse subtilties and mystical flights of his philosophical writings."

PORPHYRY, a compound rock. The art of cutting porphyry, practised by the ancients, appears to have been lost. Indeed it is difficult to conceive what tools they used for fashioning those huge columns and other porphyritic works in some of the ancient buildings in Rome. Modern tools will scarcely touch porphyry. Dr. Lister therefore thinks, that the ancients had the secret of tempering steel better than we; and not, as some imagine, that they had the art of softening the porphyry, since it is probable that time and air may have contributed to increase its hardness. Mr. Addison says, he saw a workman at Rome cutting porphyry; but his advances were extremely slow and almost insensible. The Italian sculptors work the pieces of old porphyritic columns still remaining (for the porphyry quarries are long since lost) with a brass saw without teeth. With this saw, emery, and water, they rub and wear the stone with infinite patience. Many persons have endeavoured to retrieve the ancient art, and particularly Leon Baptista Alberti, who, searching for the necessary materials for temper, says, he found goat's blood the best of any; but even this avails not much; for in working with chissels tempered with it, sparks of fire came much more plentifully than pieces of the stone. The sculptors were thus, however, able to make a flat or oval form; but could never attain to any thing like a figure.

In the year 1555, Cosmo de Medicis is said to have distilled a water from certain herbs, with which his sculptor, Francesco Tadda, gave his tools such an admirable hardness and so fine a temper, that he performed some very exquisite works with them, particularly our Saviour's head in demi-relief, and Cosmo's head with that of his duchess. The very hair and beard, how difficult soever, are here well conducted; and there is nothing of the kind superior to it in all the works of the ancients; but the secret appears to have died with him. The French have discovered another mode of cutting porphyry, namely, with an iron saw without teeth, and with *grez*, a kind of free-stone pulverized, and water. The authors of this invention say that they could form the whole contour of a column, if they had matter to work on. Others have proposed to harden tools so as to cut porphyry, by steeping them in the juice of the plant called bear's breech or brankursine. (See Birch's *Hist.* R. S. vol. i. p. 238. vol. ii. p. 73, &c.) Mr. Boyle says, that he caused porphyry to be cut by means of emery, steel saws, and water; but he observes, that in his time the English workmen were ignorant of the manner of working porphyry, and that none of them would undertake to cut or polish it. (See his Works abr. vol. i. p. 11.)

Da Costa supposes, and perhaps with reason, that the method used by the ancients in cutting and engraving porphyry was extremely simple, and that it was performed without the aid of any scientific means. He imagines, that, by unwearied diligence, and with numbers of common tools, they rudely hewed or broke the stone into the intended figure, and by continued application reduced them into more regular designs; and that they completed the work by polishing it with great labour, by the aid of certain hard sands found in Egypt. And he thinks, that in the porphyry quarries there were layers of grit or loose disunited particles, analogous to the porphyry, which they carefully sought for, and used for this work. See GEOLOGY and MINERALOGY.

PORSON (RICHARD), the greatest of the verbal critics and classical scholars of modern times, born on the 25th of

December 1759, was the son of Mr. Huggin Porson, parish clerk of East Ruston, near North Walsham, in Norfolk.

His father taught him, in his childhood, to practise all the common rules of arithmetic by memory only; and, before he was nine years old, he had learned to extract the cube root in this manner. At the same time, for teaching him to read and write, he employed the method which has since been generally introduced in the schools of mutual instruction, making him draw the letters with chalk or on sand; and the neatness and accuracy of his hand-writing, for which he was distinguished through life, may be considered as bearing ample testimony to his father's ingenuity and success.

At the age of nine he was sent to a village school, kept by a Mr. Summers; but his father still made him repeat by heart in the evening the whole of the lessons of the day; and there seems to be sufficient evidence for considering this practice of exercising the memory continually, in very early life, as the best, if not the only method of cultivating, if not of producing great talent. For though a strong memory by no means constitutes talent, yet its possession is almost a necessary condition for the successful exertion of talent in general; and, indeed, it is very possible that the other faculties of the mind may be strengthened by the early cultivation of this one. It is remarkable that Wallis, who was as deservedly celebrated in his day as Porson, for his unerring sagacity, had also a singular facility of retaining numbers and calculations in his memory, but without having taken any particular pains to acquire the habit. Mr. Hewitt, the vicar of the parish of East Ruston, hearing of young Porson's uncommon capacity, undertook to instruct both him and his brother Thomas in classical literature; and when he was about fifteen, Mr. Norris, a wealthy and respectable gentleman of the neighbourhood, having ascertained the truth of the reports that he heard of him, resolved to be at the expense of sending him to Eton. Without this assistance it would have been impossible for Porson to have acquired great excellence in any intellectual pursuit; for his father's situation in life was not such as to exempt his son even from the subordinate occupations of the country. He went out gleaning, in the autumn, with a Horace in his pocket; and he had learned by experience to appreciate the mechanical labours of Penelope, before he was much acquainted with the wisdom and wanderings of Ulysses.

At Eton, his talents procured him the friendship and admiration of the seniors amongst his schoolfellows, and, upon the unfortunate death of his first patron, Mr. Norris, he found a number of liberal contributors, who stepped forward to supply the deficiency; but by far the most active of them was Sir George Baker, then President of the Royal College of Physicians, a man as much distinguished by his own classical taste and acquirements, as by his laudable disposition to cherish learning in others. He received the boy into his house for a vacation, and undertook, at the request of a relation of Mr. Norris, the disagreeable task of receiving, in small sums, as much as was sufficient to purchase an income of L.80 a-year, for a few years, in the short annuities, which served, with great economy, to enable him to remain at Eton. This favour appears to have been too great to be properly acknowledged, or perhaps even duly appreciated, by its object, who only after many years paid Sir George the tardy compliment of a dedication, not, however, of an edition, but of a handsome copy of a single play of Euripides. In his own opinion, Porson learned little at Eton besides the quantity of syllables, being able to repeat by heart before he went there the principal part of the authors that he had to read; that is, almost the whole of Horace and Virgil, the *Iliad*, and many parts of Cicero, Livy, and the *Odyssey*. A story is accordingly told of his book having been changed by one of his schoolfellows in joke, when he was going up to a lesson in Horace, and of his having read and translated what was required of him, without at all betraying the change to his master. At the same time, the emulation of a public school must have been a great advantage to him, as affording him a motive for exertion in his exercises, whether they were to be called his own, or to be written for other boys. It was a copy of Toup's Longinus, presented to him as a reward for a good exercise, that first gave him a decided inclination for the pursuit of critical researches; but he always considered Bentley and Dawes as his great masters in criticism.

In 1777 he was sent to Trinity College, Cambridge, and at first he began to apply more particularly to the mathematics, which had been the favourite study of his boyhood, and in which, as he himself remarked, his proficiency first brought him into a certain degree of public notice. He was, however, soon diverted from this pursuit, although he attained a place amongst the *senior optimes* of his year. But he was in fact more calculated for classical than for mathematical excellence. His memory would have been in a great measure thrown away, if he had been employed in abstract calculations; and his inventive powers do not appear to have been at all of the same class with his retentive faculties; although certainly in the mechanical pursuit of the fashionable methods of modern analysis, which are intended, like steam engines, to overcome all difficulties by the inanimate force of mere patience and perseverance, he was capable of filling as distinguished a place as any living algebraist. The classical prize medal, and the university scholarship, he obtained without difficulty, as matters of course. The exercise, which he exhibited upon the examination for the scholarship, is the well known translation of an epitaph into Greek iambics; which, although not free from some inaccuracies in the use of the tenses, is still a very remarkable production, when it is considered as having been completed in less than an hour, with the help of Morrell's *Thesaurus* only, and never afterwards corrected.

He obtained a fellowship of Trinity College in 1781, and took his degree of Master of Arts in 1785; but not thinking it right to subscribe the Articles of the Church of England, he could not enter into orders, and he was therefore unavoidably deprived of his fellowship in 1791, having no dependence left for his subsistence through life, but his own abilities and acquirements. His friends, however, did not abandon him on this urgent occasion, and in order to keep him out of actual want, a private subscription was set on foot, to which Mr. Cracherode was one of the principal contributors, and by which enough was raised to purchase him an annuity of about L.100 a-year for life. A small addition was made to his income, about two years afterwards, by his election to the Greek Professorship at Cambridge, with a salary of only L.40 a-year. The situation, however, gave him the option of at least doubling his whole receipts, by the delivery of an annual course of lectures in the university; and it was supposed that he would have made this exertion, if he had not been discouraged by the difficulty of obtaining rooms in his college, where it would have been his wish to reside.

Porson married, in 1795, Mrs. Lunan, a sister of the late Mr. Perry, well known as the editor of the *Morning Chronicle*, but he had the misfortune to lose his wife two years afterwards. Mr. Perry continued to be his greatest friend through life, and was so far his best benefactor, as he knew how to oblige him essentially, without the appearance of doing him a favour. Porson had sometimes chambers in the Temple, and sometimes he lodged at the *Morning Chronicle* office; frequently also he was a visitor at Mr. Perry's house at Merton, where he had the misfortune to leave several of his books, at the time of a fire, which destroyed them all, and amongst them some letters of Rhunkenius, with whom he had begun a correspondence in 1783, and who had committed to him some valuable fragments of Æschylus, besides his manuscript copy of the lexicon of Photius, which had cost him ten months' labour. He used indeed to say that this fire had destroyed the fruits of twenty years of his life; but he had the resolution to complete a second copy of the Photius, which is now in the library of Trinity College. His fondness for the mechanical employment of his pen has been regretted by some of his biographers, as having tempted him to waste much of his most valuable time on a trifling amusement; but in fact, his mode of writing Greek was fully as much calculated for expedition as for beauty; and those who have not been in the habit of correcting mutilated passages of manuscripts, can form no estimate of the immense advantage that is obtained, by the complete sifting of every letter, which the mind involuntarily performs, whilst the hand is occupied in tracing it; so that, if the correction of Photius was really worth the labour of two years of Porson's life, it would have been scarcely possible to employ the greater part of those years more advantageously, than by copying him twice over. Mr. Weston, in speaking of "his matchless penmanship," has observed, not very intelligibly, that "here, indeed, he thought himself surpassed by" another person "not in the stroke, but the sweep, of his letters." What Porson really said on this subject was, that, with respect to "command of hand," that person had the advantage, but he preferred the *model* on which his own hand was formed. His writing was, in fact, more like that of a scholar, whilst the method explained in Mr. Hodgkin's *Calligraphia* exhibits more the appearance of the work of a writing master; holding, however, a middle place between the neatness of Porson, and the wonderful accuracy of the country schoolmaster who made the fac simile of the Oxford Pindar in the British Museum.

Upon the establishment of the London Institution, his friends obtained for him the very desirable appointment of principal librarian, with a salary of L.200 a-year, and apartments in the house of the Institution, which was then in the Old Jewry; but although the arrangement was highly honourable to all parties, the librarianship was little more than a sinecure. Porson was, however, in the habit of attending in his place when the reading-room was open, and of communicating, very readily, all the literary information that was required, by those who consulted him respecting the object of their researches. Had the inhabitants of Finsbury Square and its neighbourhood been more disposed to classical studies, and had the librarian of the Institution survived, to witness its completion and prosperity, his sphere of utility would, without doubt, have been greatly extended.

But it must ever be lamented that Porson's habits of life had unfortunately been such as to lay a foundation for a multitude of diseases. He suffered much from asthma throughout the year 1808; his memory began to fail him a little; and in the autumn he had some symptoms of intermittent fever. On Monday the 19th of September he had an apoplectic attack in the street, and he was carried to a neighbouring poor house in a state of insensibility. The next day an advertisement appeared in one of the papers, relating the accident, and describing some manuscripts which were found in his pocket, consisting of Greek fragments and algebraical characters. His friends at the London Institution immediately went in quest of him; he was afterwards well enough to appear in the library, and to receive a visit there from Dr. Adam Clarke; but his speech was impaired, and his faculties evidently imperfect. He survived only through the week, and died in his forty-ninth year, on Sunday the 25th of September 1808, at midnight.

He was buried at Cambridge, in Trinity College Chapel, near the grave of Bentley, and the monument of Newton. He founded by will an annual prize, to be given to the best Greek translation from an English dramatic author; and several specimens of the successful pieces have been published from time to time in the *Classical Journal*. His books were sold by auction, and many of them found purchasers at high prices, especially such as were enriched with any of his manuscript notes in their margins; but more than two hundred of these, which appeared to be the most valuable, were withheld from the sale, and were afterwards purchased, together with the whole of his manuscript papers, by the Society of Trinity College, for the sum of a thousand guineas. He left a sister, married to Mr. Siday Hawes, of Coltishall, Norfolk. His brother Thomas kept a boarding-school at Fakenham, and died, without issue, in 1792: his second brother, Henry, was a farmer in Essex, and died young, leaving three children. His father had lived to 74, his mother to 57.

The principal works of Porson are his *Letters to Travis*, his four plays of Euripides with their prefaces, and the manuscript copy of Photius; the rest, though somewhat voluminous, are chiefly miscellaneous annotations upon detached passages of a multitude of ancient authors. We find nothing in the nature of theory, or of the discovery of general laws, except some canons, which he has laid down, chiefly as having been used by the Greek tragedians in the construction of their verses. These are chiefly contained in the preface to the *Hecuba*, together with its supplement. 1. The first is, that when a tragic iambic ends with a trisyllable, or a cretic, this word must be preceded either by a short syllable, or by a monosyllable. For example, an ancient tragedian would not have written the line Ἔχοι δὲ μήποτ᾽ ἐξ ἀπευκτοῦ δώματος, though it might have been unexceptionable in a comedy. It seems to have been about the year 1790 that Porson first made this observation. He certainly did not attend to it in his own serious translation of the *Epitaph on Alexis;* but it was mentioned, in 1791, by one of Porson's intimate friends, in a moment of conviviality, whilst he was somewhat characteristically attempting to fill his glass out of an empty bottle; and the author of this article observed in answer, that it would certainly sound better, on such an occasion as then occurred, to say, Πᾶν ἐκπέπωκας· οὐδ᾽ ἜνεσΤΙ κότταβος, than οὐ λελειπΤΑΙ κότταβος. 2. The second canon is, that an anapaest is only admissible in a tragic iambic, as constituting the first foot, except in some cases of proper names. This indeed had been cursorily hinted by Dawes. 3. The same critic had also remarked, that the Attic poets never lengthen a short vowel before a mute or aspirate, followed by a liquid, or a middle consonant followed by ρ; and Porson more amply confirmed the observation as very generally, though not universally correct. On the other hand, Dawes had cursorily observed that Homer, and the other ancient epic poets, generally lengthened the vowel in such cases, and Porson's great rival, Hermann, has more fully established this distinction, as affording a good criterion of antiquity. 4. There are also some original remarks of Porson on the caesura, in iambics, and trochaics, and anapaests. He showed that the scenic poets do not elide the final iota, and that the tragedians do not employ the preposition περὶ before a vowel; and some other general laws, of greater importance than these, may probably be found in some of his publications, which it will now be necessary to enumerate in the order of time.

1. His first attempts, as an author, consisted of some anonymous articles in Dr. Maty's *Review*, beginning with a part of Shutz's *Æschylus*, June 1783, *Tracts* ii. Brunck's *Aristophanes*, July 1783, *Tracts* iii.; *Mus. Crit.* ii. 113; written in a day. In Latin, by Schäfer, *Class. Journ.* v. 136. Weston's *Hermesianax*, April 1784, *Tracts*, iv. Huntingford's *Apology for his Menostrophics*, August 1784, *Tracts* v. *Account of the Learned Pig*, April 1785, *Tracts* vi. *Note*, with letters of Le Clerc and Bentley, April 1786, *Tracts* vii.

2. He added some *Notes* to an edition of Xenophon's *Anabasis*, published by Nicholson, at Cambridge, 4to and 8vo, 1786. They are addressed *Lectori si quis erit.*

3. *Three Panegyrical Epistles to Sir J. Hawkins, Gent. Mag.* August, September, and October, 1787. *Tracts* ix.

4. Notes on *Toupii Emendationes in Suidam.* Oxford, 8vo. 1790. Written in 1787.

5. *Letters on the Three Witnesses, Gent. Mag.* Oct. and Dec. 1788. Feb. April, May, June, Aug. 1789. Feb. 1790. The last was reprinted in *Tracts* xix.; most of the others in the collection of *Letters to Mr. Archdeacon Travis*, in answer to his defence of the *Three Heavenly Witnesses*, London, 1790, 8vo. These letters are generally considered, by critics of all parties, as finally decisive of a question, which had often been agitated before, but never so learnedly argued, nor so satisfactorily discussed in all its bearings.

6. In the *Monthly Review*, Robertson's *Essay on the Parian Chronicle*, Jan. 1789, *Tracts* xiii.; satisfactorily answering the principal part of the objections alleged against the authenticity of that monument. Edwards' edition of the work attributed to Plutarch, *on Education*, July 1793, *Tracts* xxi. Payne Knight's *Greek Alphabet*, Jan. 1794, *Tracts* xxiii. Pybus's *Sovereign*, Dec. 1800; an article affording a good specimen of his talent for humour.

7. He is supposed to have written some *Remarks* on an *Essay upon the Transfiguration*, but never expressly acknowledged them. *Tracts* xv.

8. He added a few short *Notes* to the London edition of Heyne's Virgil, 8vo, 1793, for which he made an agreement with the bookseller to correct the press; but he complained that his corrections were disregarded; and in fact several hundred errors, of no great importance, were suffered to disfigure it.

9. He corrected the Greek text of Æschylus for the Glasgow editions, the folio of 1795, and the two volumes octavo, printed in 1794, but only published at London in 1806. The folio is said to have appeared surreptitiously. There are more than two hundred original corrections, and a further number of passages pointed out as corrupt.

10. In the *Morning Chronicle* he published, at different times, a variety of spirited articles of a temporary nature. One of the most amusing was the *Nursery Song* in Greek iambics, 13th of April 1796, called *A Fragment of Sophocles*, and signed "S. England," in ridicule of Ireland's pretended discoveries.

11. *Imitations of Horace. Spirit of the Public Journals*, 1797. *Class. Jour.* iv. 97.

12. The first four plays of Euripides appeared separately at different periods. The *Hecuba*, London, 1797, 8vo. Cambridge, 1802, with a Supplement and additional notes; which were also published separately, London, 1808. *Orestes*, London, 1798, 1811. *Phoenissæ*, London, 1799, 1811. *Medea*, Cambridge, 1801; London, 1812. The four together, London, 1822.

13. *Collation* of the Harleian manuscript of the *Odyssey* for the Grenville *Homer*, Oxford, 1800, 4to; with some short notes. Reprinted, *Class. Jour.* ix.

14. Of the *Review of Wakefield's Lucretius*, in the *British Critic* for May 1801, the principal part appears to be Porson's.

15. *A Letter signed by J. N. Dawes, Monthly Mag.* Dec. 1802, on some Greek constructions; admitting also an inaccuracy of his own with respect to a hiatus, pointed out by Mr. C. Falconer.

16. *A Letter to Professor Dalzel*, dated September, 1803; *Mus. Crit.* i. p. 326; in answer to some remarks published in the Professor's *Collectanea Majora;* with an Epigram respecting Hermann, in Greek and in English.

17. *Herodotus*, Edinburgh, 1806. Porson corrected the press for the first volume.

18. *Supplement to some Indices, Tracts* xxxvi.

19. It is well known that Porson bestowed considerable pains on the restoration of the text of the *Rosetta Stone.* His *Supplements* were added to the plates engraved by the Society of Antiquaries; and they also appear amongst his *Tracts*, xxxvii. In Dr. Clarke's *Greek Marbles*, Cambridge, 1809, 8vo, we find a translation of this inscription, communicated to the editor by Porson, and printed from "a *corrected copy* in his own beautiful handwriting." But we may here venture to apply Porson's favourite remark on the facility of transposition, and to read "a *copy corrected* in his own writing," that is, on the margin of Mr. Gough's translation, as published in *Duane's Coins.* For the whole is very negligently performed; and it is not a little remarkable that this translation, which was at least approved by Porson, is decidedly less accurate than the Latin translation of Heyne, as appears from the investigation of the enchorial inscription published in the sixth number of the *Museum Criticum.*

20. A variety of Porson's fugitive and miscellaneous pieces have reappeared at different times in the *Classical Journal. Authors cited by the Scholiast on Plato*, ii. 619, *Tracts*, xxxviii. *The Epitaph*, iii. 233; more correctly than in the *Tracts*, but still with a gross error in the punctuation of the last line, which stands, in a manuscript copy of his own, Τέθνηχ', ὃ δὴ τάχιστα πάσχοντ' οἱ 'γαθοί. This reading, though not very elegant, is at least more defensible, than to make πάσχειν alone signify to die, and a phrase to end with ὁ δή. A *Charade* in Latin, vii. 248. Some *Notes on Æschylus*, vii. 456; viii. 15, 181; x. 114. *A property of the lines* employed in the 47th proposition of the first book of *Euclid*, p. 401. *Notes on Apollonius Rhodius*, xviii. 370.

21. *Adversaria.* Cambridge, 1812, 8vo, consisting of *Notes* on the Greek Poets, selected from his manuscripts, and arranged by Professor Monk and Mr. C. J. Bloomfield. The first article is an interesting *Lecture on Euripides*, delivered upon his appointment to the Greek Professorship. It is followed by a few miscellaneous observations, and by a large collection of *Notes* on Athenaeus, on Euripides, on the *Fragments of the Tragic and Comic Poets*, on Stobaeus, and on a variety of poets of miscellaneous descriptions. The volume was reprinted at Amsterdam, without any alteration, but the sale of the foreign edition has never been permitted in Great Britain.

22. *Tracts and Miscellaneous Criticisms*, collected and arranged by the Rev. T. Kidd, M. A. London, 1815, 8vo. Besides the articles already noticed as reprinted in this volume, there are a few *Notes on Dawes's Miscellanea Critica*, not before published, No. 51. There are also some supplementary pages of *Simplicius and Cebes*, reprinted by Porson, for the use of his friends, as restored by Schweighäuser. The want of this leaf of the manuscript of *Simplicius* had given rise to the mistaken assertion that Xenophon was proclaimed a public benefactor at the Olympic Games, on occasion of the return of the ten thousand. There are likewise some miscellaneous *Notes* on Athenaeus, Menander, and Philemon, Aristides, Pausanias, and the lexicographers, and some *Indices* of authors quoted by the Scholiasts.

23. *Notae in Aristophanem*, quibus Plutum comoediam adjecit P. P. Dobree. Cambridge, 1820, 8vo.

24. Gaisford *Lectiones Platonicae.* Accedunt R. Porsoni *Notae ad Pausaniam.* Oxford, 1820, 8vo.

25. *Photii Lexicon.* Cambridge, 1822, 8vo.

To attempt to form a just estimate of the merit of such a man as Porson, without servilely following the dictates of common fame, or blindly adopting the opinions of others, is a task of no small difficulty, even to one who had the advantage of his personal acquaintance for the last twenty years of his life. But it may safely be conceded to common fame and to partial friendship, that he was one of the greatest men, and the very greatest critic, of his own or of any other age. "Nothing came amiss," says Mr. Weston, "to his memory. He would set a child right in his twopenny fable book, repeat the whole of the moral tale of the *Dean of*

Badajoz, a page of Athenaeus on cups, or of Eustathius on Homer, even though he did every thing to impair his mental faculties." It cannot, however, be denied, that the talents, and even the industry, that he possessed, might have made him a much greater man, had they been employed in some other department of human intellect. He might *probably* have been as great a statesman or as great a general as he was a scholar, and in these capacities his acquirements would have affected the interests of a much greater multitude of his fellow-creatures, than can ever be benefited by the fruits of his erudition; and he might *possibly* have gained more popularity as an orator or a poet, than his refined investigations of grammar and prosody could ever procure him, although it is not by any means certain that his fancy and invention could have been rendered by any cultivation at all comparable to his memory and acuteness. But as far as regards the possession of a combination of the faculties which he did cultivate, he appears to have been decidedly the most successful of any man on record in the same department. On the other hand, it must be admitted that the subjects of his pursuits were in their nature incapable of raising a man to the first rank amongst the permanent benefactors of the human race; and, if we calmly consider the ultimate objects of prosody and metre, it will appear almost unfair to allow the discoverer of the prosodiacal rules, adopted by the ancient poets in their melodrames and choruses, to rank so very high amongst the luminaries of an age, and yet to look down, with so much contempt as we are accustomed to do, on the character of a modern *Dieu de la danse*, notwithstanding that he thought himself the third great man of his day, with Voltaire and the King of Prussia, for having given soul and sentiment to the measures and movements of the choric representations of the present times.

Amongst the talents of Porson, however, which were so far superior to the importance of the objects on which they were employed, we ought not, perhaps, to consider his remarkable strength of memory as the most to be envied, since many persons who have been possessed of singular and almost miraculous, not to say morbid, memories, have been but little distinguished by any other faculty. It appears to be possible that a memory may in itself be even too retentive for real practical utility, as if of too microscopic a nature; and it seems to be by a wise and benevolent, though by no means an obvious arrangement of a Creative Providence, that a certain degree of oblivion becomes a most useful instrument in the advancement of human knowledge, enabling us readily to look back on the prominent features only of various objects and occurrences, and to class them and reason upon them, by the help of this involuntary kind of abstraction and generalization, with incomparably greater facility than we could do, if we retained the whole detail of what had been once but slightly impressed on our minds. It is thus, for example, in physic, that the experienced practitioner learns at length to despise the relation of individual symptoms, and particular cases, on which alone the empiric insists, and to feel the value of the Hippocratic system of "attending more to the prognostic than the diagnostic features of disease;' which, to a younger student, appears to be perfect imbecility. And it is perhaps for some similar reason that many persons, besides Barnes, "of happy memory," have had to wait long in darkness for "the day of judgment." But it must be repeated, that Porson's judgment and acuteness were really almost paramount to his memory; and with the addition of these faculties, his memory naturally rendered him capable of much that would have been impossible without it.

The respect that is justly due to classical learning has frequently been exaggerated in this country, partly, perhaps, on account of the awe which is naturally entertained, by an ingenuous mind, for its instructors in the earliest studies, by which it is advanced towards maturity. And classical learning having most wisely been placed by our ancestors the foremost, in the order of a liberal education, which is most commonly adopted in Great Britain, a personal as well as a general respect has been involuntarily paid to the characters of the individuals concerned, and to the dignity of all those who are engaged in similar occupations; besides that, the means being, by a most frequent inattention of the human mind, confounded with the end for which they are sought, the words and syllables, and the phrases and measures of the Greek and Latin authors have often been the almost frivolous occupation of a valuable life, instead of that of a few of the years of boyhood, which it was intended to devote to them, and which could not have been so well engaged in any other way. It is, however, wholly unjust to stigmatize the study of the classics, and of languages in general, as being confined to words instead of things; for it is utterly impossible that words can be learned, without the acquisition of a considerable degree of knowledge of the things to which they relate, and of the historical facts which they have been employed to express, and without an involuntary modelling of the mind to the elegance and elevation of sentiment, which pervade the works of those authors who are habitually put into the hands of boys in the course of their elementary studies; an acquirement which is of still greater value to the orator and the statesman, than the command of language, and facility of expression, and beauty of imagery, and power of reasoning, which he derives from a perfect familiarity with the great masters of antiquity. But granting all the respect that can possibly be claimed for ancient literature, we cannot but lament that such a man as Porson should have lived and laboured for nearly half a century, and yet have left little or nothing to the world that was truly and originally his own.

After the full admission of the very high rank which is due to the comparative merits of Porson's talents and acquirements, it may be thought almost idle, if not invidious, to dwell on any trifling exceptions to their magnitude. But it is, in fact, of high importance to the progress of human knowledge, to be aware of the degree in which the first of mankind are liable to error. The admission of the few errors of Newton himself, is at least of as much importance to his followers in science, as the history of the progress of his real discoveries. And it is with reason that the detection of an error in such a man is considered as almost paramount to the establishment of a new fact. The English critics have been reproached, and not without some foundation, as paying too servile a deference to Porson's opinions; and it seems to have been very generally believed amongst them, that it was scarcely possible for him to commit an error or an oversight.

Although Porson was in many respects irregular, and often idle, or even intemperate, yet what he did perform as a critic, may be allowed to leave a large balance, at the end of his life, in favour of his general industry, when compared with that of most of his countrymen. It has indeed been asserted, and perhaps with truth, (*Classical Journal*, xxi.) that "with things Porson appears to have possessed but a very inconsiderate acquaintance; and not a trace is to be found amidst his writings, of that combination of universal encyclopædiacal knowledge with language learning which is so abundantly found in the *Dissertation on Phalaris*, and the countless pages of Scaliger, Salmasius, and Casaubon." Certainly, however, neither Salmasius nor Casaubon, with all their learning, much less Scaliger, with all his industry and parade, nor even Bentley himself, with all his talent and acuteness, was at all comparable to Porson in his own department, that is, as a sound, and accurate, and refined Greek critic.

But it must be confessed, that at Cambridge, even although Porson had resolved to make the classics his principal study, and although there had not yet been many instances of senior wranglers, who were also senior medallists, it was scarcely reputable for a man, with his undeniable abilities, to be only the twenty-first of his year in mathematics. Amongst the literary objects also, which afterwards engaged his attention, he might easily have found time for the study of some of the modern languages; and he might have derived essential benefit from it on many occasions of critical research. He had, indeed, read a good deal of French, but very little Italian. He had studied the Anglo-Saxon, but he knew nothing of the kindred dialects of the north of Europe, in which it is preserved almost entire; and he was wholly unacquainted with Oriental literature. He might have profited materially by some of these studies, in deriving from them a clearer conception of the distinctions of the tenses than he seems to have possessed, and he might have enlightened us in no small degree, with respect to the history of languages and of nations, by such etymological investigations as his comprehensive mind, thus employed, would have rendered him peculiarly capable of pursuing with success.

It has been candidly and very truly admitted by a rival critic in Germany, that Porson committed fewer errors than almost any other person; but it is right to be aware that he has now and then committed some errors, even where he would have been expected to be the most correct. There is, for example, a very strange oversight in one of the criticisms contained in his early review of Weston's *Hermesianax*, which implies a palpable blunder with respect to the gender of a participle, Ζωρὸν μετροῦσα ϑυῶν πορφυρέης Λυσβιον ἐὲ ὑέλου, "the cup of purple glass, which *measured* the fragrant wine;" and even in a subsequent correction of the same passage, published in his *Adversaria*, he has changed the gender of an adjective in a way that is at least very unusual, if not wholly without example, μετροῦν θυόεντα. A mere omission, in a criticism on another author, would scarcely be called an error in an ordinary person; but in such a critic as Porson, it is very remarkable that he should have neglected to notice, in his catalogue of the *Errors of Le Clerc*, omitted by Bentley, (*Adv.* p. 291,) the grossest of all Le Clerc's blunders, which is the quotation of the word *Hypophauli* or *semibarbarous*, from Pollux, with the translation *Sartagines*, or *frying pans;* whilst the real text of Pollux simply and plainly states that the *Teganismi* or *fricassations*, in the *Hippocomus Menander*, is *a semibarbarous word*. These instances, which have occurred in a very cursory perusal of some of Porson's works, would certainly not deserve to be noticed in a general sketch of his character, any otherwise than as exceptions to his perfect infallibility.

It can scarcely be considered as an imperfection in the constitution of Porson's mind, that he wanted that amiable vanity, which is gratified by the approbation even of the most inconsiderable, and which delights to choose for its objects the most innocent and the most helpless of those who are casually present in society. It has been observed that he would neither give nor take praise; and when he was told that somebody had called him a giant in literature, he remarked that a man had no right to tell the height of that which he could not measure. In fact, having learned "to know how little can be known," it is not surprising that he found himself "without a second, and without a judge;" and that he was unwilling to affect a community of sentiment, and an interchange of approbation with those whose acquirements and opinions he felt that he had a right to despise. It might have been wiser, in some instances, to conceal this feeling; but, on the other hand, he had perhaps occasion for something of the habit of retreating into his conscious dignity, from his deficiency in those general powers of ephemeral conversation, which are so valuable in mixed societies; for, with all his learning and all his memory, he was by no means prominent as a talker. He had neither the inclination nor the qualifications to be a fascinating story teller, or to become habitually a parasite at the tables of the affluent; but he was the delight of a limited circle of chosen friends, possessing talent enough to appreciate his merits, and to profit by the information that he afforded them.

There has not yet been a life of Porson that has collected all the particulars that would deserve to be recorded by a biographer, who undertook the task on an extensive scale; but of detached documents there is no deficiency. Mr. Kidd has pointed out almost every work in which his name has been mentioned. The most material articles relating to him will be enumerated here.

Morning Chronicle, 6th October 1808. *A Short Account of the late Mr. Richard Porson, with some particulars relative to his extraordinary talents;* by an admirer of great genius (the Rev. S. Weston,) Μηκέτι πάπταινε κόρσιον, Look for nothing beyond him. London, 1808, 8vo. Republished, with some additions, under the title of *Porsoniana, or Scraps from Porson's Rich Feast*, London, 1814, 8vo. Bloomfield's *Sapphic Ode, Class. Journ.* i. 1. *Some anonymous Iambics*, p. 81. *Sale of his Library*, p. 385. *Athenæum*, iv. 426, 521; v. 55. *Class. Journ.* ix. 386. London, 1815, 4to. Kidd's *Imperfect Outline. Tracts*, 1815. Chalmers's *Biographical Dictionary*, xxv. London, 1816. L. L.

PORT, a harbour, river, or haven, formed either by nature or art to receive and shelter shipping from the storms and waves of the open sea.

Artificial ports are those which are either formed by throwing a strong mound or rampart across the harbour's mouth to some island or rock, or erecting two long barriers, which stretch from the land on each side like arms or the horns of a crescent, and nearly enclose the haven. The former of these are called *mole-heads*, and the latter *piers*.

PORT, is also a name given on some occasions to the larboard or left side of the ship, as in the following instances. Thus, it is said, "the ship heels to port," that is, stoops or inclines to the larboard-side. "Top the yard to port," the order to make the larboard extremity of a yard higher than the other. "Port the helm," the order to put the helm over the larboard-side of the vessel. In all these senses this phrase appears intended to prevent any mistakes happening from the similarity of sounds in the words *starboard* and *larboard*, particularly when they relate to the helm, where a misapprehension might be attended with very dangerous consequences.

PORTS, the embrasures or openings in the side of a ship of war, wherein the artillery is ranged in battery upon the decks above and below.

PORTADOWN, a thriving post-town, in the county of Armagh, Ireland, 66 miles from Dublin. It is situated on the Upper Bann, navigable here for vessels of 60 tons burden, and is by it connected with the Newry Canal. It has of late years been much improved, and its appearance is now highly respectable. The principal trade is in the agricultural produce of the surrounding country, which is forwarded to Newry by the canal, whilst the returning barges bring slates, coal, iron, &c. for the inland market. A good number of hands are employed in the linen and cotton trade. The population in 1831, amounted to 1,591.

PORTAFERRY, a sea-port town, on the eastern shore of the entrance into Strangford Lough, county of Down, Ireland, 80 miles from Dublin. It consists of a small square, a few streets, a range of houses on the quay, and several places for public worship. The principal trade is carried on with the Liverpool and Glasgow markets, for the agricultural produce of the neighbourhood. The population in 1821 was 1512, and in 1831, 2203.

PORTAL, in *Architecture*, a little gate where there are two gates of a different size; also a little square corner of a room cut off from the rest by the wainscot, and forming a short passage into the room. The same name is also sometimes given to a kind of arch of joiners' work before a door.

PORTALEGRE, a city of Portugal, in the province of Alentejo, the capital of a corregimiento of the same name. It is situated on a hill about seven miles from the frontiers, and strongly fortified, being defended by a citadel and many extensive outworks. It is the see of a Bishop, who has a fine cathedral, and under his care an ecclesiastical seminary. There are in this town four parish churches, and five religious houses, with some charitable institutions. It contains 1127 dwelling-houses, with 5780 inhabitants, who make a large quantity of woollen cloth, especially such as is adapted for the troops; and there are carried on some other branches of manufacture.

PORT ANNA MARIA, a bay or harbour on the south coast of Sir H. Mertin's island, in the South Pacific Ocean, seven miles west of Point Mertin. Long. of the entrance 139, 39. W. Lat. 8. 30. S.

PORTARLINGTON, a borough town, situated in King's County and Queen's County, Leinster, Ireland. It is 44 miles from Dublin, and is situated on the river Barrow, which divides it into two parts, and it consists principally of one long street, about two miles in length. The houses are generally large, and regularly built; but the town possesses neither commerce nor manufactures, nor is it situated on any high road of communication. The prosperity of the town depends on a greater proportion of gentry residing in it, than is generally to be found in towns of its size in Ireland; and also on the reputation of its schools. There are two Protestant churches, a Methodist, and Roman Catholic chapel. The borough possessed, before the year 1784, a large property; but the corporation in that year, and in the year 1802, conveyed over to Lord Portarlington, the patron of the borough, the whole of the property, which brings yearly to the noble proprietor L.800 sterling, and for which he pays to the corporation the sum of L.60 late Irish currency. The borough is governed by a sovereign, two bailiffs, and a recorder, and it returns one member to parliament. The population in 1821, amounted to 2877, and in 1831, to 3091.

PORTATE, or a Cross Portate, in *Heraldry*, a cross which does not stand upright, as crosses generally do, but lies across the escutcheon in bend, as if it were carried on a man's shoulder.

PORT-AU-PRINCE, the capital and seat of government of the republic of Hayti, formerly called St. Domingo or Española, one of the West India Islands. It stands at the bottom of the large bay of the same name, in a situation so low and marshy as to render the climate very unhealthy. It is mostly built of wood; the streets are broad but unpaved; nor are any of its edifices remarkable for their architectural elegance. It contains the president's palace, several literary and scientific institutions, a lazaretto, and some other public buildings. There is an academy for medicine, astronomy, law, literature, and other branches of knowledge; a drawing seminary, Lancasterian and primary schools, and a national library. There is also a military school, where the pupils receive instruction gratuitously; and several newspapers and periodical journals are published here. The city is supplied with water by a conduit three English miles in length. It has a spacious and secure port and roadstead, where five hundred vessels may anchor at once. It is surrounded by hills which command the town and harbour; and both the hills and the vallies are abundantly fertile. To the east is situated the noble and celebrated plain of Cul de Sac, extending from thirty to forty miles in length, by nine in breadth. It is chiefly laid out in sugar plantations, most of which can be watered in times of drought by means of canals admirably adapted for the purpose. Commerce is the principal occupation of the inhabitants of Port-au-Prince. The amount of imports may be estimated at twenty millions of francs; but the exports, consisting chiefly of coffee, cotton, Campeachy wood, sugar, and other articles, are much greater. This city was founded in the year 1745; but twenty-five years afterwards it was almost completely destroyed by an earthquake. It was rapidly rebuilt, but was nearly reduced to ruins by fire in 1791. In 1830, it again experienced several shocks of an earthquake, some of which did considerable damage. The inhabitants of the district of Port-au-Prince are estimated at about 90,000, and those of the city at about 30,000. Lat. 18. 34. N. Long. 72. 27. W.

PORTCULLIS, in *Fortification*, is an assemblage of several large pieces of wood, joined across one another like a harrow, and each pointed with iron at the bottom. They are sometimes hung over the gate-way of old fortified towns, ready to be let down in the case of surprise, when the gates cannot be shut.

PORT-DALRYMPLE, a harbour or estuary on the north coast of Van Dieman's Land, in which the Tamar discharges itself, after receiving the North and the South Esk. At the union of the latter it is navigable for vessels of 150 tons.

PORTER, a kind of malt-liquor which differs from ale and pale beer, in its being made with high-dried malt. See Brewing.

PORT-GLASGOW, a sea-port town of Scotland, is situated on the south bank of the Frith of Clyde, in the shire of Renfrew, about nineteen miles below Glasgow, and three above Greenock. This place originally formed part of the adjoining parish of Kilmalcolm, and consisted of the small village of Newark, so called from the barony of that name, which lay in its immediate vicinity. On a point of land projecting into the river, a little above the town, is situated the ancient and now deserted castle of this barony. The ground on which the town stands was, in 1668, purchased from Sir Patrick Maxwell of Newark, by the magistrates of Glasgow, with a view to provide a convenient harbour for the vessels belonging to the merchants of that city. A harbour was therefore constructed, and streets were laid off, according to a regular plan. In 1695 the place was, by the competent authority, detached from the parish of Kilmalcolm, and, with a few adjacent farms, erected into a distinct parish, approaching in form nearly to a square, and not exceeding an English mile either in length or in breadth. It was called New Port-Glasgow, or more commonly Port-Glasgow, a name simply expressing the design of its erection as the port or harbour of Glasgow. In 1775 it was created a borough of barony; and by the reform act of 1832 it became a parliamentary borough of the third class, uniting with Kilmarnock, Rutherglen, Dumbarton, and Renfrew, in returning a member.

Port-Glasgow is one of the most handsome and regularly built sea-port towns of Scotland. The streets are straight, and for the most part cross each other at right angles; whilst the houses, pretty nearly equal in size, and generally whitewashed, give to the whole a light and uniform appearance. The only buildings worthy of particular notice are the town-house and the parish church. Of these the former is of plain but substantial workmanship, ornamented in front with a portico, resting on four massy fluted columns, surmounted with a handsome spire, which rises from the centre. The parish church was built in 1823. It is square in form, and plain in outward appearance, but is deservedly admired for the simple elegance of its internal construction. A commodious chapel of ease belonging to the establishment was built in 1774. The only other place of worship in the parish belongs to the Associate Synod.

The land of this parish church lies along the bank of the river, having been long occupied as gardens, presenting a rich and highly cultivated appearance. The town itself is romantically situated at the bottom of a hill, which, covered with wood and verdure, exhibits a beautiful object to travellers passing along the river.

Attached to this port are two capacious harbours, substantially built, and completely sheltered from the storm. The first dry or graving-dock in Scotland was constructed here in 1762, and has since been improved at great expense. Some years ago, the harbour accommodation having been found too small, the inhabitants resolved to avail themselves of their local advantages, by converting the bay of Newark, which is naturally adapted to the purpose, into a spacious dock, where vessels of the largest class might be kept securely afloat in every state of the tide. Accordingly, in June 1830, the trustees of the harbour obtained an act of parliament, investing them with the necessary powers; and the work, which was contracted for by Mr. Gibb, an eminent architect, was commenced in the spring of 1834, and carried on with every dispatch until 1836, when a small portion of the outer wall gave way. In consequence of this untoward incident, the operations were considerably impeded, and it was even deemed expedient to erect a ruble breakwater, to enable the trustees to restore the outer wall so soon as the works had been allowed sufficient time to consolidate. As a substitute for the outer wall, and in order to secure the full benefit of the wet-dock, the trustees have, in the mean time, resolved to construct a wooden wharf on the outside. The works having since been considered as sufficiently consolidated, and the inner walls having afforded abundant evidence of their stability, the necessary sheds, together with the wharfs alluded to, have lately been contracted for, and are at present in rapid progress; so that this important undertaking, which has cost its enterprising promoters about L.40,000, may now be considered as completed. Many ships have already discharged their cargoes in it. Besides the numerous sail of merchantmen at present, (December 1838), within its walls, there is the British Queen, steam-ship, (receiving her machinery), the largest vessel ever built in the United Kingdom. This is the only wet-dock of the kind on the west coast of Scotland. It extends over a space of twelve imperial acres, is 25 feet deep, has an entrance-gate of 55 feet in width, is provided with spacious quays and commodious sheds, cranes, and other conveniences, and possesses extraordinary facilities for ingress and egress, owing to the great depth of water in the roads and entrance, and the protection afforded by the lofty hills by which the dock is sheltered. With all these advantages, in addition to an extensive tide harbour, Port-Glasgow now affords shipping accommodation of a very superior description. The charges on shipping at this port are much lower than at any other in Scotland. This is in a great measure owing to the extensive bonded warehouses held by the corporation, situated alongside the dock-walls, where every description of goods may be deposited at trifling rates.

The foreign trade of this port is chiefly with the West Indies and North America. It is the principal place on the Clyde for the importation of North American timber, for the reception of which it has large wood-ponds. Not less than 27,975 tons were imported in 1834. A comparative view of the tonnage employed in the foreign trade of the town during the last eight years indicates considerable improvement; the average inward tonnage for the four years prior to the 5th of January 1834 having been 23,901, and for the four years ending the 5th of January 1838, 28,761 tons. The harbour revenue exhibits a corresponding annual increase. In 1831, the harbour-dues amounted to L.1454; in 1834, to 1639; in 1836, to L.1800; and at present they average about L.2000 per annum. The customs collected have for the year ending in January 1838 amounted to L.94,161, a sum much less than what was received a few years ago. But the deficiency is not to be attributed to any decline of trade; for under the existing laws the amount of customs collected at any warehousing port forms no criterion for ascertaining the real extent of its commerce. The deficiency is attributable to two causes, which bear no direct reference to the decline or the improvement of trade; namely, first, the collection at Glasgow since the year 1834, of the duties upon tobacco, which were formerly paid here; and secondly, the facilities afforded by recent laws for recovering bonded goods from the port of importation without payment of the duty. Thus, merchandize of every description, although imported here, is daily removed under bond to other places, where the duties are paid, which causes a diminution of the customs paid at this port, and may at first sight lead to the inference that the commerce of the place is declining, whilst, in point of fact, it is on the increase.

The coasting trade of Port-Glasgow was at one time very considerable; but owing to the great facility with which vessels of inferior burden now find their way up the river, nearly the whole of this branch has been transferred to Glasgow.

The work of ship-building is carried on here to a considerable extent. Of late years the carpenters have been chiefly employed in the construction of steam-boats, of which they have produced a great number, some of them of the largest class, and all of them of remarkable symmetry and superior workmanship. The manufacture of ropes and sail-cloth has been prosecuted for about a century. A considerable trade is carried on in sugar-refining.

In 1700 the population was not more than 400 souls; but in 1718, the inhabitants amounted to twice that number. From this period the population continued steadily, though not rapidly, to increase until the year 1790, when it consisted of 4036 persons. At each of the four decennial censuses which have since been taken, it was as follows:—In 1801, 3865; in 1811, 5116; in 1821, 5262; and in 1831, 5192. From a survey which was taken expressly for the New Statistical Account, in the summer of 1835, it was ascertained that the population had increased to 6018. The comparatively slow increase of population in this place, and its occasional falling off, as above indicated, are referable to the fluctuations of foreign trade, and to the depressing influence of the neighbouring ports of Greenock and Glasgow.

PORTGREVE, or Portgrave, was anciently the principal magistrate in ports and other maritime towns. The word is formed from the Saxon *port*, a port or other town, and *geref*, a governor. It is sometimes also written *portreve*. Camden observes, that the chief magistrate of London was anciently called *portgreve;* but instead of him, Richard I. appointed two bailiffs; and soon afterwards John granted them a mayor as their yearly magistrate.

PORTICI, a palace of the king of Naples, six miles from the capital, and charmingly situated on the sea-shore, near Mount Vesuvius. It is enriched with a vast number of fine statues, and other remains of antiquity, taken out of the ruins of Herculanum. See Pompeii.

PORTICO, in *Architecture*, a kind of gallery formed on the ground; or a piazza encompassed with arches supported by columns, where people walk under covert. The roof is usually vaulted, but sometimes flat. The ancients called it *lacunar*. Though the word *portico*, be derived from *porta*, a gate or door, yet it is applied to any disposition of columns which form a gallery, without any immediate relation to doors or gates.

PORT-JACKSON, a bay and English settlement on the east coast of New Holland. The two heads through which the entrance lies are distant from each other one mile and three quarters; and the heads on each side are high, steep, perpendicular cliffs, between which ships may run in safety. It may be entered in all winds. Within, the port divides into two branches, the one stretching eighteen miles west, the other seven miles north-west. Both contain numerous creeks, on one of which is situated the town of Sidney, the chief town of Botany Bay. Long. of Castle Point, 151. 11. 49. E. Lat. 33. 51. 45. S.

PORTLAND, a town of Maine, one of the United States of North America. See Maine.

Portland, an island on the coast of Dorsetshire, or rather a peninsula, since it is joined to the mainland by a lofty bank of pebbles, which runs parallel to the sea, about three miles in length. Within the beach is a small arm of the sea, called the Fleet, the passage over which, by a ferry, is the common communication with Weymouth, from which it is distant about three miles. The island is a solid mass of stone, peculiarly adapted for buildings of the first class; and the extracting it from the quarries, and placing it on vessels, form the chief employment of the inhabitants. The surface of the rock is covered with a soil, the herbage of which feeds a small race of sheep, celebrated for the delicate flavour of their flesh. Some cows are also kept, and a small part of the land yields corn, but not sufficient for the inhabitants. The parish comprehends seven hamlets. It has a church near the centre; and towards the south end is the well constructed light-house, so important to navigation. Portland road is a secure anchorage, and is defended by a small fort. Lat. of the light-house 50, 31. 22. Long. 2. 26. 59. W. The population was in 1801, 1619; in 1811, 2079; in 1821, 2254; and in 1831, 2670.

Portland Islands, is a cluster of small islands in the Eastern Seas, to the westward of New Hanover. They were so named by Captain Cintenet in 1767. The north-east point of the most eastern isle, is in Long. 147. 18. E. Lat. 2. 36. S.

Portland Island, in the South Pacific Ocean, is situated near the east coast of New Zealand. Long. 178. 12. E. Lat. 39. 25. S.

Portland vase, a celebrated funeral vase, long in possession of the Barberini family, but which was purchased for a thousand guineas by the Duke of Portland, from whom it derived its present name. Its height is about ten inches, and its diameter where broadest six. There are upon it a variety of figures of most exquisite workmanship, in bas relief, of white opaque glass raised on a ground of deep blue glass, which appears black except when held against the light. It seems to have been the work of many years, and there are antiquarians who date its production several centuries before the Christian era; since sculpture was declining in excellence even in the time of Alexander the Great.

PORT LOUIS, a fortified sea-port of France, in the department of Morbihan, and arrondisement of L'Orient. It is situated at the mouth of the river Blavet, on the bay of its own name, and is inclosed by the sea on three sides. It has a citadel of great strength, three churches, a naval hospital and exchange, 365 houses, and 3480 inhabitants. Lat. 47. 45. Long. 3. 32. W.

PORT-MACQUARIE, an inlet on the east coast of New Holland, into which falls the river Hastings. It received its present appellation from Mr. Oxley, who surveyed it in 1818. Long. 152. 53. 54. E. Lat. 31. 25. 115. S.

PORT-ROYAL, a town of the island of Jamaica. See Jamaica.

PORT-SANDWICK, a harbour of the island of Mallicollo, in the South Pacific Ocean. Long. 167. 67. E. Lat. 16. 25. S.

PORTOBELLO, a parliamentary burgh, situated on the Frith of Forth, nearly three miles from Edinburgh. The town is neatly built, and as the beach is extensive, and commodious for sea-bathing, it is consequently much frequented in the summer season as a watering-place. It is not a place of trade, but has several manufactories for making bricks, tiles, and potteries, a crystal and glass work, and one or two others of less importance. The town is governed by a provost, two baillies, and six councillors; and, with Leith and Musselburgh, it returns a member to parliament. The stationary population in 1821, amounted to 1912, and in 1831, to 3170.

PORTOBELLO, a town situated on the isthmus of Panama. See Panama.

PORTO FERRAJO, the capital of the Island of Elba, in the province of Pisa, and the duchy of Tuscany, celebrated as the residence of Napoleon during his banishment to that island. It is situated on a tongue of land running into the sea, and forming a small bay. It is fortified, and contains two churches, an hospital, 600 houses, with 3120 inhabitants, who depend chiefly upon some salt works and the tunny fishery. Lat. 42. 49. 6. Long. 9. 20. 15. E.

PORTO-NOVO, a sea-port town of the south of India, in the Carnatic. It is esteemed the safest port on the Coromandel coast. The ground is good, and vessels may anchor in six fathoms water. In August 1781, the British gained a victory here over Hyder Aly. Long. 79. 52. E. Lat. 11. 30. N.

PORTO RICO, or Puerto Rico, one of that group of West India islands called the great Antilles, and the smallest of the four in population and extent, but yielding to none in fertility and general importance. It is situated to the east or windward of Hayti, Cuba, and Jamaica, being separated on the west from the first named island by a channel twenty-five leagues in breadth, and having the Atlantic Ocean on the north, with the Carribean Sea on the south. It is about ninety miles in length from east to west, by thirty-three miles in average breadth; and contains, according to an exact admeasurement, a plane superficies of 2970 square miles.[1] A chain of lofty mountains intersects it from east to west; the highest part, called Luguilla, at the north-east extremity of the island, being 1334 Castillian yards in height. Valleys, levels of table land, and gentle declivities, all highly fruitful, are every where found embosomed in these mountains; and they are themselves susceptible of cultivation to the very tops. To the north and south of this interior ridge, situated between it and the sea coast, are those richly fertile valleys which produce the chief wealth of the island. They are formed by smaller ridges of hills, which run north and south from the principal chain, and are much more level than those situated amongst the loftier mountains, which present an unequal, undulating surface, and a continued succession of gentle acclivities, covered with trees displaying all the varied colours and vivid foliage of the tropics. The valleys of the north and east coasts are the richest in cattle, and the most picturesque, the pasturage there being always verdant and luxuriant, from the abundant supply of rain which they receive; whilst those of the south coast, richer than the north in sugar, are often parched by excessive drought. This, however, can easily be remedied, for water is found by digging only half a yard below the surface of the ground. Few countries of the same extent as Porto Rico are watered by so many streams. Seventeen rivers, taking their rise in the mountains, cross the valleys of the north coast and fall into the sea. Some of them are broad and deep, and navigable for two or three leagues from their emboucheurs, which, however, are much obstructed by bars. These rivers are well stocked with excellent fish; and the banks of the whole of them are nearly all under cultivation. The south, west, and east coasts are well supplied with water, notwithstanding the unfrequency of rain. There are several large streams, besides numberless rivulets, and branches of navigable water. Porto Rico therefore possesses great natural facilities for inland navigation, particularly upon the north coast. Of course we find the year divided in this island, as in the others belonging to the West Indies, into the wet and dry seasons, the former the winter, the latter the summer. But this distinction does not give a proper idea of the seasons in Porto Rico; for on the north coast it sometimes rains during the whole year, whilst on the south coast a perfect deprivation of rain for twelve or fourteen months is no uncommon phenomenon, even when in the mountains there are daily showers. The climate of the north and south coasts of this island, therefore, are essentially different, although under the same tropical influence. The only difference of temperature to be observed throughout the whole island, is between the valleys and the mountains, which happens in every country similarly situated. In the mountains the inhabitants enjoy the coolness of spring, whilst the valleys, were it not for the daily breeze which blows generally from the north-east and east, would be uninhabitable. In August the atmosphere is oppressively hot, the thermometer being frequently above 90° of Fahrenheit; and during the coldest season it is never below 70°. In September the rains descend like a deluge, and the rivers swell and overflow their banks, completely inundating the low lands, whilst the smallest brooks become deep and rapid torrents. In October the weather becomes cooler, and in the following month the north and north-east winds generally set in, diffusing an agreeable coolness through the atmosphere. When the fury of the north wind abates, the most delightful weather is experienced. Hurricanes, the scourge of the West Indies, sometimes visit this island, generally between the months of July and October. In the year 1825, one occurred on the 27th of July, which nearly laid it desolate. Notwithstanding the general heat of the climate, and the humidity of some parts of Porto Rico, it is reckoned healthy. The number of mountains and running streams, the absence of stagnant water, and the general cultivation of the land, no doubt powerfully contribute to purify the atmosphere and render it salubrious to man. This island exhibits a singular scarcity of indigenous animals. There are no venomous snakes or reptiles, no beast of prey, or indigenous quadrupeds of any kind to be found in the forests, scarcely any of the feathered tribes, and no noxious insects. But rats of an enormous size and in great numbers infest the country, and sometimes commit dreadful ravages upon the sugar canes.

---

[1] These are the dimensions assigned to the island by Colonel Flinter in his *Account of the Present State of the Island of Puerto Rico*, 1834. Malte Brun, on what authority does not appear, makes it one hundred and twenty miles in length by forty in breadth; and other geographical writers extend its longitudinal dimensions still further. Probably the discrepancy arises from extreme points being taken in the one case, whilst a medium measurement is that given by Colonel Flinter, who had the most ample means of knowing every thing connected with the island. To his work on Porto Rico we have been chiefly indebted for the present account of it.

The principal wealth of Porto Rico consists in agriculture. No manufactories are carried on, and no mines of gold and silver have been explored, if such exist. The soil is of the richest description, and a prolific and luxuriant vegetation covers every part of the island. The agriculturist is not limited by the nature of the soil to the exclusive cultivation of any particular produce. Every species of fruit and vegetables, congenial to tropical climates, may be planted with the certainty of reaping an abundant harvest. The best and most luxuriant pasture for rearing cattle; the rich, deep, vegetable mould necessary for the sugar cane; the humid soil in which the cocoa vegetates; and the cool mountain glades, so congenial to the coffee plant, may all be found within a small circle. Cotton, tobacco, and indigo, the latter being a spontaneous product of the fields, only require a little attention to render them objects of importance.

The whole agricultural riches of the island, houses, lands, and slaves, not included, were valued in 1832 at 37,993,599 dollars, and the produce at 6,883,371 dollars; of which there were exported through the custom houses to the value of 3,411,845½ dollars. The contributions levied on this property amounted only to 266,526 dollars, which is less than 3¼ per cent. on the value of property, and less than 5⅞ per cent. on the value of produce. We have no doubt that the value of property and produce is much greater than what has just been stated; for as the people of the country themselves make the valuation, they always endeavour to make it appear as small as possible, in consequence of the direct tax levied on property.

Colonel Flinter thinks that there cannot be fewer than two hundred thousand horned cattle on the island, the other animals being proportionally more numerous than they appear to be from the statement given; and he thinks that the total value of the cattle may be estimated at 7,858,774 dollars. A great traffic has long been carried on in them, with the English, French, and other settlements. They bring a higher price than those of South America, in consequence of being fattened from the finest pasture land in the world, and from their extreme tameness. Vast quantities of raw and tanned hides are likewise exported. The production of sugar is the next great branch of industry. That the soil and climate are admirably adapted for the cultivation of the cane will be seen from the following fact. The proportion of sugar produced from the land employed in its cultivation, is in Jamaica and Dominica, ten quintals per acre; in Grenada, fifteen quintals per acre; in St. Christopher's and Tobago, twenty quintals per acre, and in St. Vincent's, twenty-five quintals per acre; whilst in Porto Rico it is estimated at thirty quintals per acre.

Notwithstanding the great natural resources of this island, there are imported, besides manufactured goods, considerable quantities of provisions and other articles, of which, by attention, Porto Rico might be made itself to yield sufficient supplies. However, an examination of the exports and imports shows, that of late years, the produce of the land exported, considerably exceeds the value of goods and provisions imported.

Amount of Exports and Imports for several years.

Years.	Imports. Dollars.	Exports.	Difference in favour of Exports.	Amount of Duties.
1810	1,005,694	662,570	...	...
1828	2,039,928	2,590,726	550,798	522,034
1830	2,208,941	3,411,845	1,202,903	...

In 1830, there entered about 60,000 tons of shipping, of which one-half belonged to America, one-fourth to Spain, and the remaining fourth chiefly to England, France, and Denmark. The importations from America, which in value amount to one-third of the whole, consist of salt fish, flour, butter, lard, grain, lumber, boards, staves, and articles of furniture. The mother country exports her olives and brandies, her wines and dried fruits, oils of olive and almond, carpets for kneeling on, and other manufactures, alputc, anchovies, and so forth. England imports cotton goods, Irish linen, hardware, earthen-ware, and the like; and France imports linens, cambrics, ladies' dresses and ornaments, toys and jewellery. Foreign goods pay seventeen per cent. of importation duties, *ad valorem*; and an export duty of six per cent. is levied on all goods sent from the island, with the exception of timber and live stock, which are charged much higher. Spanish vessels from the peninsula pay six per cent. of importation duty, and the export tax is also much less than it is for foreign vessels. It is scarcely necessary to say, that the exports from Porto Rico consist of live stock, sugar, coffee, tobacco, and the other rich productions of the island. Colonel Flinter states his conviction that the value of the exportations and importations exceeds the amount which appears in the custom-house returns; for goods are undervalued in general, and a considerable contraband trade is carried on. The nett revenue of the island in 1832 amounted to 798,404 Spanish dollars (each equal to 4s. 3¾d sterling), and the expense of maintaining the civil and military establishments, amounted to 630,300 dollars; thus leaving a balance in the treasury, of 168,104 dollars. The taxes, although levied in an obnoxious manner, being for the most part direct, are comparatively light. In 1832, the direct taxes produced 207,141; the custom-house duties, 493,930; and the indirect taxes, 97,333 dollars. The government, laws, and institutions of this island, are nearly similar to those formerly established by the kings of Spain in every part of the western hemisphere. There is a regular military force stationed on the island, and likewise a strong disposable body of well-disciplined militia.

Porto Rico contains fifty-eight towns and villages, thus giving nearly one to every six square leagues. The largest place is San Juan, the capital. It is finely situated on the slope of a hill, on the north coast of the island. The streets, which run parallel and cross each other at right angles, are perfectly straight, and run down to the side of the bay. It is enclosed on every part by strong fortifications, which render the town almost impregnable. It is considered as one of the best and healthiest towns in the West Indies. It is adorned by a number of useful public edifices and institutions. Amongst these may be mentioned, the cathedral, a large mass of building, which has never been finished; four churches, two chapels, three convents, an episcopal palace, and a seminary for the education of the clergy; the royal military hospital, a large stone edifice, and an establishment of the same kind for females; the government house, called the fortress of Santa Catalina, which has stood for upwards of two hundred years; the royal goal, a large stone edifice; a house of correction; a large and handsome town-house; a beautiful theatre, built at the public expense; a custom-house; an arsenal, and some others. A society, called the Economical Society, is established for promoting the fine arts. There is also a mathematical class; whilst two schools for boys, and one for girls, are paid for by the municipality. There is an excellent and secure harbour, and a commodious wharf. This town is the residence of the governor, and the Catholic bishop, and here all the principal courts are held. San Juan was founded in the year 1514. Within a century afterwards it was twice taken and plundered by the English, who, however, could gain no permanent footing on the island, neither at these times nor at a later period under General Abercromby. The population is estimated at 30,000.

Some of the provincial towns may be considered as large with reference to the extent of the island; such as Mayagues and Aguadilla on the west coast, Pouce on the south, Pepino and Cayey in the interior, and Humacao on the eastern coast. The other towns and villages, with few exceptions, are merely skeletons, containing a large square, with the church, the houses of the curate and magistrate, the militia quarters, and a few residences of wealthy people. There are fifteen ports in which custom-houses and receptories have been established. By far the greater number of the inhabitants are scattered over the island in agricultural establishments. The total number will be seen from the following table:

Statement of the Population of the Island of Porto Rico, from the year 1778 *to* 1830, *inclusive, according to the official returns made to the Spanish Government.*

Years.	Whites.	Free people of colour.		Total free of colour.	Slaves.	Total coloured population.	Total population of the island.	Ratio of increase.
		Mulatoes.	Blacks.					
1778 to 1802	78,281	55,164	16,414	71,578	13,333	84,911	163,192	132 per cent.
... 1812	85,662	63,983	15,823	79,806	17,536	97,342	183,014	12 ditto.
... 1820	102,432	86,269	20,191	106,460	21,730	128,190	230,622	26 ditto.
... 1827	150,311	95,430	25,057	120,487	31,874	152,361	302,672	40 ditto.
... 1830	162,311	100,430	26,857	127,287	34,240	161,527	323,838	6½ ditto.

This shews an extraordinary rate of increase; and allowing that the population has augmented in the same ratio since the last census was taken, we may safely estimate the number of inhabitants of this island in 1839 at about four hundred thousand souls. The island of Bieques, situated three leagues from the north-east coast of Porto Rico, is under the command of the captain-general of the latter. It is ten leagues in length, by two in breadth, and reckoned one of the most fertile spots in the West Indies. It has several commodious ports and harbours, and from its position to the windward might be made of considerable importance to Porto Rico, if properly settled, which it is not.

Porto Rico was discovered by Christopher Columbus in 1493, and was supposed at the time to contain 660,000 inhabitants. Having learned that the Spaniards had made themselves masters of Española, these savages looked upon the invaders as invincible and immortal. But to put the matter to the test, they tried an experiment on one of the domestics of Columbus, and finding that he was mortal, they rose upon the Spaniards, and made a great slaughter of them, whilst employed in plundering the treasures of the natives. The Spaniards seldom required so good a pretext for retaliation, and they accordingly rose upon the inhabitants, and effected their total extermination. Since then it has been gradually settled by Spaniards; and from the census given above, it will be seen that it promises at no distant date to be as thickly peopled as it was when first visited by the prince of navigators. R.R.R.

PORTO SANTO. See Madeira.

PORTO-SEGURO, a large tract of country in Brazil, situated to the north of Rio and Espiritu-Santo. It was formerly reckoned a province of itself, but at the new provincial division of the country in 1829, it was formed into a comarca of Bahia. Along with Espiritu-Santo, it forms one continuous tract, presenting such a sameness of natural features, that they have generally been described together. It is separated from Rio de Janeiro on the south, by the river Capabuan or Itabupuana. On the west it borders on Minas Seraes; the river Belmonte separates it from Bahia on the north, whilst its eastern limits are washed by the Atlantic ocean. It has a sea-coast of four hundred miles in length; and the maritime district is the only part of the country as yet peopled by Europeans, or their mixed descendants. "The lofty and naked ridge of middle Brazil," Porto Seguro.

Porto Seguro.

says Prince Maximilian, "in the provinces of Minas Geraes, Goyaz, and Pernambuco, is divided from the eastern coast, by a broad tract of high forests, which extend from Rio de Janeiro to the Bay of All-Saints (Bahia) about eleven degrees of latitude, and which are not yet taken possession of by the Portuguese settlers; only a few roads have hitherto been opened, with infinite labour, along the rivers that traverse them. In these forests, where the primitive inhabitants, who are pressed upon at every other point, have till now enjoyed a serene and peaceful abode, we may still find those people in their original state." In fact the aborigines of Espiritu-Santo and Porto Seguro have been found more difficult to civilize than any other native tribes in this quarter of the world, and the country itself is still in a great measure uncultivated. The civilized people are wholly confined to the coast, and even there they are not perfectly secure from hostile attacks. Yet the salubrity of the climate, and the fertility of the soil, have rendered this district an object of interest with government, so that settlers have been induced to occupy it. The virgin forests with which it is nearly covered, abound with the finest timber, including the cedar, the sassafras tree, and various other resinous and aromatic species; and no province possesses such an abundance of the tree which supplies the Peruvian balsam. "In the provinces of Espiritu-Santo and Porto-Seguro," says a recent traveller, "are found several kinds of wood suited to cabinet-work and architecture. The Ibirapitanga (Brazil wood) now so necessary in manufactures, and which is beginning to fail in Pernambuco, is met with here," and, we may add, on the authority of others, in abundance.

Between the southern limits of the country and the Rio Doce, which separates Espiritu-Santo from Porto Seguro, are situated several towns and villages, and a few military posts, to secure the settlers from the inroads of the savages. About twenty miles north of the Itabupuana, on the southern bank of the river Itapemirim is a village of the same name, more recently built than the others, and containing some good houses. The inhabitants, who are but few in number, carry on a small trade in sugar, cotton, rice, millet, and timber. The Sera de Itapemirim, from which the river descends, is celebrated for the works for washing gold, called Minas de Castello, five days journey up the Itapemirim. From this place to the frontier of Minas Geraes, a road has been opened through the dangerous wilderness of woods; but it is hazardous to travel along it on account of the savage hordes of Puries and Botucudoes, by which the country is infested. From the village of Itapemirim to the village of Nova de Benevente, the country presents alternate woods and meadows, with a stream at intervals, but no river of any size. Benevente stands at the foot of a hill on the northern bank of the Iritiba or Reritigba, called also the Benevente. This place was built by the Jesuits, who here collected a great number of Indians for the purpose of civilizing them; but the hard labour exacted by the crown drove most of them to other quarters. This was the largest establishment on the coast, and the church and convent erected by the missionaries are still seen in the neighbourhood of the town. Between Benevente and the Rio de Espiritu Santo, which gives name to the province, the country is one continuous and magnificent forest, abounding with multitudes of the feathered tribes. The river Espiritu Santo, which is of considerable magnitude at its mouth, rises in the mountains on the frontiers of Minas Geraes, and descending with many windings, through the extensive ancient forests of the Tapuyas, issues forth at the foot of one of those higher chains of mountains which stretch towards the sea. According to Cazel, the proper name of this river is the Santa Marta. It is stated to be navigable to the first fall, about forty miles up, and the tide ascends twelve miles to the Serra, a river which joins it on the left. Villa Velha, a small and unimportant town, stands on the south bank of the river, not far from its mouth; and about half a league from it, on the opposite side of the bay, is the present capital of Espiritu-Santo, called Villa da Victoria. It is built, according to Cazal, on an amphitheatrical site, on the western side of an island fifteen miles in circumference. It is a pretty neat place, with considerable buildings, constructed in the old Portuguese style. The population of this city is estimated at 12,500.

From this town to the Rio Doce, the limits of Espiritu-Santo on the north, there are several rivers and small towns; but generally speaking, not only the interior but the seacoast is densely wooded. This province comprehends three-fourths of the captaincy, which, in the year 1534, was assigned to Vasco Fernando Coutinho, as a remuneration for his services in Asia. The Portuguese were repeatedly driven from the colony by the natives, but ultimately they obtained a decisive victory over the savages, and effected a permanent settlement. The Jesuits were the first who succeeded in making peace with the aborigines, and in 1551 they founded the college of Vittoria; but, as we have observed, they made little progress in this quarter.

The adjoining comarca of Porto Seguro extends from the Rio Doce to the river Belmonte. It lies between 19° 33′ and 15° 25′ of south latitude, which gives it a length of sixty-five leagues. It was upon this part of the coast that Cabral first set foot, and took possession of Brazil for the crown of Portugal. Some Portuguese having settled here, they intermarried with the natives, so that Pedro Campo Tourinho, its first donatory, found himself, in a few years, the lord of a tolerably well-peopled colony. Santa Cruza town, built on the bay where Cabral cast anchor, soon became considerable and flourished; but the settlement was afterwards transferred to the banks of the Ioâo de Tyba, four miles to the northward, no doubt from this site holding out greater advantages of soil. Besides this place, Tourinho founded the town of St. Amaro, three miles to the south of Porto Seguro, which was subsequently demolished by some of the Indian tribes. After passing through various hands, this captaincy ultimately reverted to the crown in 1758. It was then in a very wretched state, and contained only two towns. The Jesuits, with all their zeal, were able to effect but little, and at the time of their expulsion, they left only two aldeias entirely Indian. As early as 1553, they founded a college in the capital, with a view to prosecute their labours amongst the Indians of the province, but, as in the case of Espiritu-Santo, with very little success.

The Rio Doce, or sweet river, the most considerable stream between Rio and Bahia, has its origin in the mountains of Minas Geraes, and assumes the name which it bears after the confluence of the Rio Piranga with the Ribeiro do Carmo. It runs through a considerable tract of country, forming several falls in its course. The banks of this river are covered with thick forests, which are the haunt of a great number of different animals. But far more formidable than all those beasts of prey, and the terror of these forests, is the savage Botucudo, the original inhabitant of the country. Some stations have, from time to time, been formed on the beautiful banks of the Doce; but they have never thriven, from being liable to attacks by the savages, so that the country is still very thinly peopled, and no communication is kept up except along the river. From the banks of the Rio Doce to the St. Matthæus, a dreary uninhabited wilderness extends along the coast. Indeed, for more than a hundred miles the maritime district is a very flat tract of country; the dull monotony which it presents being only here and there relieved by a sheet of water, or small mountain elevation. The district of St. Matthæus contains about 3000 inhabitants, who cultivate a great deal of mandioc, and export annually 60,000 alquieres of flour, and also planks from the neighbouring forests. The orange, the lemon, and the water-melon, flourish here luxuriantly.

The river St. Matthæus, originally called the Cricare, like the other large streams in this quarter, rises in the mountains of Minas Geraes, and descends through ancient forests peopled by savage tribes, forming various falls, and receiving several rivers in its course. Cazal mentions the large stream of Cotache as joining it on the left margin. Nearly thirty miles from the St. Matthæus is the Mucuri, at the mouth of which stands the Villa de St. Joze do Portalegre. This place has of late years risen into some importance, from the opening of a road along the banks of the river, to Villa do Principe in Minas Geraes. Almost all the fine species of wood found on the eastern coast of Brazil, abound in the forests of this district. Five leagues to the north of the Mucuri, is the river Peruhipe, four miles from the mouth of which is the town of Villa Vicosa, consisting of about one hundred houses, with a church and camara, pleasantly situated amongst groves of cocoa palms. The inhabitants carry on a trade in mandioc flour, which is exported in small coasting vessels. Ten miles farther north is Caravellao, situated on a river of the same name, about five or six miles from the sea. The river is two miles in breadth, and proportionally deep; and up to the town its banks are beautifully interspersed with plantations. Caravellao is bustling and populous, and carries on a brisk trade in the productions of the country, especially mandioc flour, large quantities of which are annually exported. The port is much frequented by vessels from Pernambuco, Bahia, Rio, and the other towns on the east coast.

Porto Seguro, the capital of the comarca, is situated at the mouth of the river Buranhem, in lat. 16° 40′ south, and long. 40° 12′ west. The port, which has given name both to the town and the district, is formed by a ledge of rocks which runs out for about a mile from an extended point of the main, in a direction parallel to the land, presenting a natural mole. This town is less considerable than Caravellao, but may contain a population of about 3000 souls. The upper part of it lies on an elevated ridge, but the major portion of the inhabitants are established on the declivity nearer the river, a place more advantageous for carrying on trade. A third part of the town lies close to the mouth of the river. There is little agricultural industry displayed in this country, the greater part of the farina consumed being brought from Santa Cruz. This, with salt fish, constitutes the chief subsistence of the inhabitants. About eighteen miles north of Porto Seguro, is the town of Santa Cruz, already mentioned. It is smaller and less important than the capital, although once in a flourishing condition. Some attention, however, is paid here to agriculture; and farina is exported to various parts of the coast. The most northerly town of Porto Seguro is the Villa de Belmonte, situated on the Rio Grande de Belmonte, which falls into the sea in latitude 15° 40′ south. This town was originally an aldeia of christianised Indians, but few of them now remain, and the place has sunk into decay. The whole population of Espiritu Santo, has been reckoned at 74,000; that of Porto Seguro is probably not more. But a great part of the country is still in complete possession of several Indian tribes, amongst which the Botucudes, the remains of the once formidable Aymores, are the most conspicuous.

PORT-PATRICK, a sea-port town and parish, on the west coast of Wigtonshire, at the distance of 133 miles from Edinburgh. It is situated on the shore of the Irish Sea, at the nearest point to Ireland, the distance being only twenty-one miles to Donaghadee. From this cause, as well as from being the best place for crossing between the two countries, steam packets and sailing vessels regularly sail between the two ports with the mails from Edinburgh, London, and Dublin. The town is not large, but it is beautifully situated, with a fine southern exposure, and encompassed on the other side by a ridge of small hills, which shelters it from the cold air of the sea. The climate is therefore salubrious, and on that account is much resorted to during the summer months for sea-bathing. The harbour was formerly small and inconvenient, but very extensive improvements having been carried on by the late Sir James Hunter Blair and by government, to render the harbour fit for shipments at all times of the tide, it has, especially its quay, been made one of the best in the kingdom. The chief trade arises from the importation of cattle and horses from Ireland. The population in 1821, amounted to 1818, and in 1831, to 2239.

PORTRAIT, in *Painting*, the representation of a person, and especially of a face, done from the life.

PORTREE, is a small village, containing a church and a very few houses, with an excellent bay and a good harbour, in the isle of Skye.

PORTSMOUTH, a town of the county of Southampton or Hampshire, within the hundred of Portsdown, and seventy-four miles from London. It stands on an island divided from the mainland by a small creek or arm of the sea. This island, called Portsea, is about fifteen miles in circumference, and contains nearly 5100 acres of land of great fertility; and, besides the borough of Portsmouth, the town formerly known as Portsmouth common, but now by the name of the island, and also what may be denominated a town called Southsea, besides many other neat houses. The last of these towns has grown up to importance within a few years, because it has become a place of great resort for sea-bathing; and hence the usual accommodations of such places have been constructed and extended.

The population appears for the four decennial enumerations to have been, in the three divisions, as follows:

	1801.	1811.	1821.	1831.
Portsmouth Borough and Parish	7,839	7,103	7,246	8,083
Portsea	24,327	31,365	34,785	38,199
Portsea Guildable	1,060	2,099	3,594	4,107
	33,026	40,567	45,675	50,389

Portsea Guildable is a part of the parish of Portsea, not within the jurisdiction of the borough of Portsmouth. The limits of that borough contain within them the whole of the *town* of Portsea; and the right of voting for members of parliament was conferred on the inhabitants, occupiers, by the reform bill. The corporation now consists of fourteen aldermen and forty-two councillors, who elect the mayor. It is divided into seven wards, and has justices of the peace appointed by the Crown.

The statements of population are exclusive of the corps of royal marines and regular troops, as well as the seamen on board the ships in the harbour, which are estimated to amount to about 4000 persons.

The soil of the island is marshy, and was formerly found to be unhealthy; and besides, the inhabitants suffered much from the scarcity and dearness of good water. But of late years those evils have been remedied by complete draining of the moist parts, and by the construction of good sewers, which carry into the sea the impurities of the towns. Two efficient Water Companies have completed works for the supply of that necessary of life; and no town in England is now better supplied with it, or at a cheaper rate, than the inhabitants of Portsmouth and its vicinity. The returns of deaths show that forty years ago they were one in thirty annually of the population; whilst in the three years 1827, 1828, 1829, they did not exceed one in sixty.

The favourable situation of Portsmouth for a naval arsenal, led to the constructions that have since distinguished it, at the period when the sovereigns of England first began to form a naval force. Some of the fortifications were erected on the sea-side as early as the reign of King Henry the

Eighth; but the walls surrounding the town were first built of stone in the reign of Elizabeth. In every subsequent reign additions and improvements have been made to it.

As the town of Portsmouth is surrounded with walls, the streets are for the most part narrow, nor can it as a whole be represented as a well-built place. The High Street is of moderate breadth, and has a few good buildings; but a part of it is disfigured and contracted, by having the market house running through the middle of it. Some of the buildings are of ancient date; one especially in the High Street is worthy of observation, as having been the dwelling in which the Duke of Buckingham was assassinated, in the reign of King Charles I. It may be remarked, that the best buildings in Portsmouth are the inns and hotels, which are numerous, and proportioned to the great number and various descriptions of occasional residents arriving and departing, as passengers to and from all parts of the world. The largest pile of building is the marine barracks, capable of accommodating some thousands of soldiers; but it is absolutely without taste or ornament. The walls that surround the town are shaded with trees, and afford a good promenade to the inhabitants. Another promenade is furnished on the grand parade, where every morning the troops destined to take the guard for the day and night are assembled. From the parade, by a slope, the king's bastion is reached, where the garrison standard is hoisted every morning at break of day. At the east end of the Grand Parade is the garrison chapel, the remnant of an ancient hospital, called *Domus Dei*, built in 1238. The building has recently been taken down, and the chapel, or rather the chancel part of it, is now the only remains of the ancient erection.

At the west end of the platform, on an ancient building, which, before the dissolution of the monasteries, had been the government house, a lofty *semaphore* has been erected, from which signals are made to the ships in the harbour and at Spithead. It is also connected with a chain of telegraphs, terminating at the Admiralty Office in London, and by which communications are conveyed, so that a message has been sent and an answer received in two minutes. In a niche in the wall of this ancient building is a bust of King Charles I., with an inscription underneath, stating that "after his travels through France and Spain, and having passed very many dangers both by sea and land, he arrived here the 5th October 1623." This was on his return from the secret journey he made in search of a bride of the Spanish royal family.

The parish church is a venerable object, said to have been built originally in 1220, and dedicated to the then recently canonized St. Thomas à Becket. The chancel is the only part left of the original building, and affords a contrast, by its numerous pillars, clustered pilasters, and ribbed pointed arches in the Saracenic style, with the architecture of the nave, built in the plain Tuscan style, the pillars of which support circular arches, and carry the roof. Few places of worship in the kingdom are superior to this church in internal beauty, which is chiefly due to the elegance of the chancel, but is increased by a few painted windows over the altar, which has been recently presented to it. At the west end is the tower, added in 1693, which is 120 feet in height. Over this, in an octagon latticed erection called the lanthorn, is a fine peal of eight bells. Surmounting the whole, as a weather vane, is a gilt model of a ship, six feet long, which has a shifting flag on the mizen mast that moves with the slightest motion of the air, and indicates from what quarter the wind blows, when the breeze is not sufficiently strong to move the hull of the ship.

The walls of this church are adorned with a great variety of handsome ancient and modern monuments; one of the most remarkable of which is that to the memory of the Duke of Buckingham, whose assassination has already been adverted to. In the parish register is to be seen the registration of the marriage of king Charles II. with the Infanta of Portugal, 22d May 1662. This document, in letters of gold on vellum, is highly illuminated in the style of the old missals, and states the marriage to have been performed by Sheldon, bishop of London. Some doubts have since been suggested whether any other ceremony was used, except a private marriage by a Catholic priest.

Besides this capacious church, there is open to the inhabitants the large garrison chapel for the established worship, and four places of meeting for several sects of dissenters. In the other towns the places of worship are numerous. At Portsea, there are, for the episcopal worship, the parish church of Kingston, the dock-yard chapel, St. George's church, St. John's church, besides a Catholic chapel, a Jew's Synagogue, a Wesleyan, two Independent, and two Baptist meeting houses. In Southsea is St. Paul's church, with a Methodist and a Baptist chapel. At Landport, or a part better known as the Halfway Houses, is All Saints' church, besides no less than nine chapels of various sects. Almost all these places of worship have schools attached to them, some on Sundays and others for week days; and in addition to them is a large school, where reading, writing, and arithmetic are taught on Bell's system. A philosophical institution has been established, containing a museum of natural history and curiosities, and a choice library, rapidly increasing. At the rooms lectures are delivered on physical and moral philosophy, and on the belles lettres. There is also over the market house a mechanic's institute, where meetings are held, and weekly lectures delivered. A well endowed grammar school in Penny Street affords classical instruction to fifty boys, sons of the inhabitants of the town. The town-hall, gaol, theatre, custom-house, and the other public buildings in Portsmouth, present very little attraction.

Few markets are better supplied than that of Portsmouth. A large part of the fertile island of Portsea is laid out in kitchen and fruit gardens, from which spring crops of vegetables are grown much earlier than in other parts of the kingdom. No market produces finer meat; large quantities of poultry, hares, partridges, and eggs, are brought from France, and the extensive water communication gives facility to provide hay, corn, flour, and other articles, at very cheap rates. To this cheapness of provisions, combined with the purity of the air, and the number of comfortable houses recently built, may be attributed the great extension of Southsea which the population tables present.

The buildings in Portsea, except those belonging to the government, are by no means distinguished. The streets are regularly built, well paved and lighted, and kept generally in a clean state, but as the greater part of the inhabitants consist of artificers and labourers of different grades employed in the dock-yard, or otherwise in the public service, the houses are mostly small, conformably to the finances of the occupants. Southsea consists of houses of a more respectable class, forming terraces or rows mostly looking on the sea, and enjoying the prospect of the inner harbour, the fortresses that guard the entrance to it, and the buildings and scenery on the opposite shore. It has one distinguished pile called the *king's rooms*, consisting of an elegant suite of rooms, eighty feet in front. Within is the promenade room, forty-five feet long, thirty-five feet wide, and seventeen feet high, adapted for music or dancing; and besides, it contains baths, both warm and cold, and gives a cheerful appearance to the spot. Besides the three towns here noticed, there are groups of houses on the island, and single dwellings of various descriptions. The largest of the groups, called the Halfway Houses, from lying midway between Portsea and the parish church, has many respectable houses, as well as the new church of All Saints.

The most important view in which Portsmouth can be looked upon is as the great depôt of the British naval power, and in this view the state of the surrounding water

Portsmouth.

and of the harbour above the town, become worthy of observation and description. One of the great advantages of this place is that very fine anchorage known by the name of Spithead. It is about half way between the mainland and the Isle of Wight, but nearer to the latter. It is protected by the high land of the island from southerly winds, and from northerly and easterly winds by the mainland. It has an advantageous entrance. For, though at the east there are some dangers on what is called the Princessa shoal, and on the ranges of rocks called Bambridge's Ledge, and Betty's Ledge, they, as well as the Nab rock, the Long rock, the Warner, and Romansland, are so well provided with either floating lights or distinguishing buoys, that there is little risk, except in those very thick fogs when the buoys cannot be seen, nor the leading marks observed on the sea-shore. At this entrance it is a great advantage, that at St. Helen's, at the east end of the island, there is a good anchorage, so that if the wind takes a vessel short, she can safely ride till the breeze is in her favour. The western entrance to Spithead is by Hurst Castle, and the rocks called the Needles. This passage is always safe in fair winds, on account of the definite track which is shewn by the buoys, lights, and landmarks; but it is so hazardous, that few ships attempt in a contrary wind to beat through. The passage out by the Needles is used by more vessels than come into Spithead that way.

The anchoring ground at Spithead is very good for holding, and very clear, except near the wrecks of the Royal George, the Boyne, and the Edgar, around which the tide has formed considerable banks. There is a regular depth of water in every part, varying from six to twelve fathoms, and the space is sufficient for the whole navy of England to ride at single or double anchor, without danger of falling on board each other when swinging with the changes of the tide.

Within the smooth water, between the island and the mainland, there are other very good anchorages, besides that of Spithead. The Mother-bank is one of them, which, though there are but two fathoms of water at low tides, has near to the bank from seven to nine fathoms, where in time of war merchant ships have been collected to wait for the convoy of ships of war. Stakes Bay is another anchorage, where there is from four to nine fathoms water, and where merchant ships often anchor.

The great advantages arising from so secure a rendezvous as Spithead, so near to the great national marine arsenal, are too obvious to need any elaborate remarks. The entrance to the harbour of Portsmouth is very narrow, but with sufficient depth of water for the largest ships. The channels by which vessels approach the mouth of the harbour, are commanded by batteries of such power that an enemy's fleet, however strong, would be annihilated before it could reach even the entrance. Within the narrow gut at the entrance, on one side of which is Portsmouth, and on the other side Gosport, the water spreads out into a wide basin, in which those ships of war that are under repair, or preparing for sea, are riding, and some of them lying at the wharfs of the dock which borders the harbour on the eastern side. From thence the harbour extends into the land, and contains, in one part called Rotten Row, the ships that are in ordinary, being with no other crew but a few warrant officers, to prevent them from plunder, or from injury by weather. The water here branches off in various directions, and by the help of the tide is navigable to Farnham, and to Porchester Castle, a pile of antiquity that will reward the curiosity of a visitor.

The dock-yard of Portsmouth is one of those noble objects in which every Briton feels an interest. But this has already been described under the article Dock Yards.

The gun wharf, under the ordnance department, is an immense arsenal, consisting of various ranges of buildings for the reception of military and naval stores and artillery. Some of the storehouses are vast piles, especially two, which, with their dependencies, are fitted to contain all kinds of necessaries for the sudden equipment both of a fleet and an army. On the wharf is the grand depôt for guns, carronades, and mortars, with shot and shells of almost every weight and size, all of which are arranged in immense pyramids. Here also in time of peace the guns from the ships in ordinary at the port are lodged, each ship's guns being kept in a separate tier, whilst the carriages are deposited away in the same regular manner in the proper storehouses, so that the whole may be easily collected again and re-embarked. The small armoury is a spacious building, and the great object of admiration. Within it are upwards of 20,000 stand of arms, all placed in the same ornamental style as those of a similar description in the tower of London. The roof of this building is covered with copper, which being oxydized by exposure to the atmosphere, when viewed on approaching it from the quay gate, conveys to the mind the idea of a green glassy slope, or a still wave of the sea.

Portsoy.

The victualling establishment has recently been removed from Portsmouth to the opposite side of the harbour, and properly belongs to the town of Gosport. The expense of this depository is said to have amounted to half a million of money. The storehouses, of vast dimensions, are used as depositories for bread, beef, pork, and other articles of food, of rum, wine, and clothing, that are kept ready for the supply of the navy. A special object of curiosity at this establishment is the machinery substituted for manual labour in making biscuit, whereby every process, in its minutest detail, is effected, preparatory to its being ready for the oven, including kneading, rolling, forming, and stamping. Another object worthy of attention is a fine new steam corn mill, recently built an an expence of L.76,000.

Portsmouth is not merely a port for warlike purposes, but enjoys a considerable foreign and coasting trade. The custom-house is a large and convenient building, and in its stores merchandize may be kept under bond free of duty till it is sold for internal consumption, or is exported. The shipping belonging to the port, in which Gosport is included, consists of about 300 sail of vessels, registered at nearly 10,000 tons; some are engaged in the Newfoundland fishery, and since the trade with India has been laid open, a few vessels have landed cargoes here from beyond the Cape of Good Hope. There is a considerable importation of wine, and some of West India articles, but the chief business consists in timber, corn, Irish provisions, Spanish and Portuguese fruits, and the vine of both these countries. The amount of duty annually received on imported articles at the custom-house, is from L.50,000 to L.60,000.

PORTSOY, a burgh of barony and a sea-port town, in the parish of Fordyce, and county of Banff. It is situated on a point of land, jutting into a small bay, of the same name, on the Moray Frith, and consists of a few streets, irregularly built. The harbour is small, but safe, and is capable of admitting vessels of 150 tons. The chief trade is in linen and thread, manufactured principally for the Aberdeen, London, and Nottingham trade. Grain is also shipped from the port, and there is a considerable trade arising from the herring fishing. Portsoy is famed for the serpentine, erroneously called Portsoy marble, which is quarried to a considerable extent near the town. It is beautifully variegated, and as it is susceptible of a high polish, it is much used for ornaments. There is also found the splendid variety of flesh-coloured granite, possessing Labrador feldspar, which is nowhere else to be found, except in Arabia, where it was first discovered. The population in 1821 amounted to 1,700, and in 1831, the population of the parish and burgh was 3,364.

PORTUGAL.

History.

Ancient boundaries.

Portugal, the most westerly kingdom of Europe, is bounded on the west and south by the Atlantic Ocean, and on the east and north by Spain. By modern writers we find this country constantly styled in Latin *Lusitania;* and it is certain, that anciently a part of Spain went by that name; but it does not by any means appear that the country called by the ancients *Lusitania* had the same boundaries with the modern kingdom of Portugal. Before the time of Augustus Cæsar, Lusitania seems to have been bounded on the north by the ocean, and on the south by the river Tagus; thus comprehending all Galicia, and excluding two out of the six provinces of Portugal. But in the more strict and limited sense of the word, it was bounded on the north by the *Durius*, or the Douro, and on the south by the river *Anas*, or the Guadiana; so that it was not quite equal to modern Portugal in length, but considerably exceeded it in breadth.

Etymology of the name.

The commonly received opinion with regard to the etymology of the word *Portugal* is, that a great number of Gauls landed at Porto, or Oporto, whence it received the name of *Portus Gallorum*, or *the Port of the Gauls;* and that in process of time the name gradually extended over the whole country, being softened, or rather shortened, into *Portugal.* But the time when this event happened, the reason why these Gauls went thither, and what became of them afterwards, are all particulars which lie buried in oblivion. It is pretended, however, that, upon an eminence which overlooks the mouth of the Douro, there stood an ancient town called *Cale*, strong and well peopled, but ill suited for trade; and that this occasioned the construction of a lower town or hamlet, which was called *Portus Cale*, or the haven of Cale, and, in process of time, *Portucalia.* At length, when this place became so considerable as to be erected into an episcopal see, the bishops subscribed themselves, as the records of ancient councils testify, *Portucalenses*, the name of the city being transferred to the diocese. It is true that these bishops afterwards changed their title, and subscribed themselves *Portuenses*, or "bishops of Portu." But the facts just mentioned are actually recorded in authentic histories; and as the diocese of Portucalia in a great measure contained that little country in which the sovereignty originally commenced, the name extended itself with the acquisitions of the sovereigns, and came to be applied to the whole kingdom, though the diocese itself has changed its name.

Portugal originally only a small kingdom.

Portugal, though even yet but a small kingdom, was originally much smaller. The Spanish and Portuguese historians agree, that Don Alonso, king of Leon and Castille, and son of Don Ferdinand the Great, bestowed his daughter, Donna Theresa, in marriage upon an illustrious stranger, Don Henry, and with her gave him the frontier province, which he had conquered from the Moors, small indeed in extent, but excellently situated, and so pleasant and fertile that it has sometimes been styled *Medulla Hispanica*, or the Marrow of Spain. To this territory was added the title of Count; but authors are very much divided respecting the time when this stranger came into Spain, and who he was. The more probable opinion appears to be, that he was a grandson of Robert, the first duke of Burgundy. The manner in which he obtained the principality may be briefly related.

Henry of Burgundy the first count of Portugal.

The king, Don Alonso, apprehensive that his success in taking the city of Toledo would bring upon him the whole force of the Moors, sent to demand assistance from Philip I. of France, and the Duke of Burgundy, whose daughter he had married. His request was granted by both princes; and a numerous body of troops was speedily collected for his service, having at their head Raymond count of Burgundy, Henry, younger brother of Hugh duke of Burgundy, Raymond count of Toulouse, and many others. In the year 1087 they arrived at the court of Don Alonso, where they were received and treated with all possible marks of esteem; and having in the course of two or three years given great proofs of their courage and conduct, the king resolved to bestow his only daughter, named Urraca, then at most in her ninth year, upon Raymond count of Burgundy, and assigned them the province of Galicia for the support of their dignity. About four years afterwards, Don Alonso, being desirous to express his gratitude to Henry of Burgundy, gave him in marriage a natural daughter of his, born whilst he remained in exile at Toledo, whose name was Donna Theresa; and upon this marriage he conveyed in full property the country which has already been mentioned. The new sovereign, with his consort, fixed their residence in the town of Guimaraens, pleasantly situated on the banks of the river Ave. The remains of an ancient palace belonging to their successors are still to be seen; and on account of its having been anciently the capital, the king granted the inhabitants an immunity from taxes.

Difference with Castille.

The Portuguese, finding themselves now independent, immediately began, like most other nations, to attempt the subjugation of their neighbours. Henry is said to have performed great exploits against the Moors; but the accounts given of them are extremely indistinct and unsatisfactory. He died in 1112, and was succeeded by his son Don Alonso, then in the third year of his age. In the minority of the latter the kingdom was governed by the queen-mother Donna Theresa, assisted by two able ministers. During the first nine years of their administration nothing remarkable happened; but, after that period, some differences took place between the queen regent and Urraca queen of Castille. Theresa insisted that some part of Galicia belonged to her in virtue of her father's will, and therefore seized upon Tuy, an episcopal town, and a place of some consequence. Urraca, having assembled a numerous army, proceeded in person into Galicia, where Theresa was obliged to abandon Tuy, and take shelter in one of her own fortresses. The consequence would probably have been fatal to the new kingdom, had not the archbishop of Compostella, without whose assistance Urraca could perform nothing, demanded leave to retire with his vassals. This offended the queen so much that she threw him into prison; an act of violence which excited such a commotion amongst her own subjects, that the Portuguese were soon delivered from their apprehensions. Theresa immediately afterwards fell into a similar error, by throwing into prison the archbishop of Braga, who had not espoused her cause so warmly as she expected. The bishop, however, was quickly delivered by a bull from the pope, who also threatened the kingdom with an interdict. Soon after this, Urraca died, and all differences were amicably settled at an interview between Theresa and Don Alonso Raymond, who succeeded to the kingdom of Castille. But, in 1126, the king of Castille being obliged to march with the whole strength of his dominions against his father-in-law, the king of Aragon and Navarre, Theresa took the opportunity of again seizing upon Tuy; but the king having soon returned with a superior army, she was again obliged to abandon her conquest.

Alonso's wars with the Moors and king of Castille.

But the greatest misfortune which befell this princess was a quarrel with her own son, Don Alonzo Enriquez. It does not appear indeed that Theresa had given him any just cause of offence; but it is certain that a civil war ensued, in which the queen's forces were totally defeated, and herself made prisoner, a situation in which she continued during the remainder of her life. Enriquez having thus attained to the free and full possession of his dominions, made several attempts upon various places in Galicia, but without success; and he was at last constrained to conclude a peace with Alonso, king of Castille and Leon, who had assumed the title of *Emperor of the Spains*, more especially as his dominions happened to be at that time invaded by the Moors. The number of infidels was so great that the Count of Portugal had but little hopes of subduing them; but a plague having broken out in the Moorish army, they were obliged to retreat, after which he reduced several places belonging to that nation. In the mean time, the Emperor Don Alonso, having made an irruption into the Portuguese territories, destroyed everything with fire and sword. The king of Portugal surprised and cut off a considerable part of his army; but this did not prevent the emperor from marching directly towards him. At the intercession of the pope's legate, however, all differences were accommodated, a peace concluded, and all places and prisoners taken on both sides were delivered up.

Victory of Ourique.

Meanwhile, the progress of the Christian arms in Spain being reported to Abu-Ali Texefien, the miramamolin or chief monarch of the Moors in Barbary, he directed Ishmael, his lieutenant in Spain, to assemble all the forces in the southern provinces, and to drive the Christians beyond the Douro. Ishmael immediately began to prepare for putting these orders in execution; and having added a considerable body of troops which had arrived from Barbary to those whom he had raised in Spain, the whole army was very numerous. He was met by Don Alonso of Portugal on the plains of Ourique, upon the banks of the river Tagus, where Ishmael took all possible means to prevent the Christians passing that river, because his own cavalry, in which consisted the strength of his army, would thus have more room to act. The Portuguese forces were inconsiderable in number in comparison with the Moors; but Ishmael, being too confident of victory, divided his army into twelve bodies, and disposed them in such a manner as might best prevent the flight, not sustain the attack, of the Christians. The consequence was, that his army was overthrown with incredible slaughter, and a vast number of prisoners taken, amongst whom were one thousand Christians of the sect styled Mozarabians, whom, at the request of Theotonus, prior of the Holy Cross, Don Alonso set at liberty with their wives and children, and procured them settlements in his own dominions.

Don Alonso assumes the title of king.

After this signal victory, gained in the year 1139, Don Alonso was proclaimed king by his soldiers, and ever afterwards retained that title, renouncing all kind of subjection to the crown of Spain. Being very desirous, however, of reducing the power of the emperor, he formed a league with Raymond, count of Barcelona, and regent of the kingdom of Aragon, against that prince. In virtue of this treaty, he entered Galicia with a considerable force on one side, whilst Don Raymond simultaneously invaded it on the other. But neither of these enterprises succeeded. The Portuguese monarch met with a severe check in his expedition into Galicia, where he received a dangerous wound, whilst some of the nobility who attended him were taken prisoners. At the same time, having received intelligence that the Moors had invaded his dominions, he was obliged to retire; but his retreat was not made in sufficient time to prevent the strong fortress of Leiria from falling into their hands. This fortress they demolished, and put the garrison to the sword; but the king caused it to be reconstructed of greater strength than before, and placed in it a more numerous garrison. Yet he undertook nothing farther during this campaign. The war continued with various success till the year 1145, when the king projected an enterprise against Santarem, a strong city, at no great distance from Lisbon. In this he luckily succeeded, and thus gained a considerable tract of country, with a strong barrier to his dominions.

After this success Don Alonso caused himself to be crowned king of Portugal before an assembly of the states, where he also solemnly renounced all dependence upon the crown of Spain; declaring, that if any of his successors should condescend to pay tribute or to do homage to that crown, he ought to be deemed unworthy of enjoying the kingdom of Portugal. The next year the king undertook to recover Lisbon from the Moors; but there are so many fables related of this expedition that it is impossible to come at the truth. All that can be gathered from these accounts is, that he undertook the siege with a small army, and was able to make little progress in it, partly from the strength of the place, and partly also from the numerous garrison by which it was defended. At length, fortunately for Don Alonso, a fleet of adventurers, French, English, Germans, and Flemings, who were on their way to the Holy Land, having anchored at the mouth of the Tagus, he demanded their assistance, as not altogether foreign to their design of making war upon the infidels. His request was readily granted; and, with their assistance, Lisbon was speedily reduced; a conquest which so much enhanced the reputation of this monarch, and brought such numbers to recruit his army, that before the end of the year 1147 he had reduced twelve other considerable cities.

Reduces Lisbon and other cities.

His regal dignity confirmed by the pope. War with Don Ferdinand of Spain.

For many years after this, Don Alonso was successful in all his undertakings. He settled the internal government of his kingdom; procured a bill from Pope Alexander III. confirming his regal dignity; undertook many successful expeditions against the Moors; and became master of four out of the six provinces which compose the present kingdom of Portugal. In all his undertakings he was assisted by the counsels of his queen, Matilda, a woman of great capacity, and capable of governing the kingdom in her husband's absence. By her he had a numerous offspring, including three daughters, the eldest of whom, Donna Matilda, was married to the king of Aragon; the second, Urraca, to Don Ferdinand king of Leon; and the third, Theresa, to Philip earl of Flanders. In 1166, however, the king thought proper, from what cause we know not, to invade the dominions of his son-in-law Don Ferdinand, and to seize upon Limmia and Turon, two cities of Galicia, in which he placed strong garrisons. Elated with his success, he next year marched with a numerous army towards Badajoz, which he invested. On receiving the news of this attack, Don Ferdinand, who had assembled a large army at Ciudad Rodrigo, marched to its relief. But before he came in sight of the fortress it had surrendered to the king of Portugal; upon which Don Ferdinand resolved to besiege his antagonist in his newly-conquered city. Don Alonso perceiving his design, endeavoured to draw out his forces into the field. Though at that time upwards of seventy years of age, he placed himself on horseback, and pushing forward at the head of his horse to get out at the gate, struck his leg against one of the bolts with such violence that the bone was shattered to pieces. This accident occasioned such confusion that the Portuguese troops were easily beaten, and Don Alonso was taken prisoner. He was exceedingly mortified by this reverse, especially as he had no great reason to expect kind treatment from his son-in-law. However, the king of Leon behaved towards him with the greatest respect and affection. He desired him to lay aside all thoughts of business, and attend to his cure; but finding him restless and impatient, he assured him that he expected nothing more than to have things put into the same condition as before the war, and that in future they should live in peace and friendship. To this proposal the king of Portugal most readily assented; but he returned to his dominions before his cure was perfected, and thus became lame all the rest of his life. This, however, did not abate his military ardour; for his courage transported him into the field whenever he was called thither by the interests of his subjects. Towards the end of his reign, an opportunity seemed to present itself of obtaining once for all an entire release from the disagreeable pretensions of the king of Leon, who, it seems, had insisted on the king of Portugal doing homage for his kingdom. This was a quarrel between the king of Leon and his nephew Don Alonso king of Castille. The latter solicited assistance from the king of Portugal, which was readily granted. But Don Ferdinand having received intelligence that the infant Don Sancho, the king's eldest son, was advancing towards Ciudad Rodrigo, assembled his troops with such diligence on that frontier, that being enabled to attack him unexpectedly, he entirely defeated him.

Don Sancho's success against the Moors.

Understanding, however, that Don Sancho was recruiting his forces with great diligence, he suggested that they might be much better employed against the infidels, who remained careless and unprepared, expecting the issue of the contest. Don Sancho did not fail to profit by this advice; and after some movements intended to amuse the enemy, he made a sudden irruption into Andalusia, penetrating as far as Triana, one of the suburbs of Seville. The Moors assembled their forces in order to attack him on his retreat; but Don Sancho having first fatigued them by the celerity of his march, at length chose a strong camp, and, having given his troops time to repose, drew them out and offered the enemy battle. The Moors accepted the challenge, but were entirely defeated; and Don Sancho returned to Portugal loaded with spoil. For some years afterwards the war continued without producing any remarkable event; but, in 1184, Joseph king of Morocco having already transported multitudes of men from Barbary, at length followed in person with a prodigious army, and carried all before him as far as the Tagus. He appeared before the city of Santarem; but having exhausted and reduced his army by unsuccessful assaults on that place, he was attacked by the Portuguese assisted by Ferdinand of Leon, and entirely defeated and slain. By this victory the Portuguese were left at liberty to improve the interior of their country, and to fortify their frontiers; but not long afterwards, that is, in the year 1185, the king died, in the seventy-sixth year of his age.

Wise administration of Don Sancho I.

Don Alonso was succeeded by his son Don Sancho I. Of this prince it is remarkable, that before he ascended the throne he was of a restless and warlike disposition; but no sooner did he come to the possession of the kingdom than he became a lover of peace, and began with great assiduity to repair the cities which had suffered most by the war, and to repeople the country around them. By his steady attention to the work of restoration, he in a short time quite changed the appearance of his territories, and procured to himself the glorious title of The Restorer of Cities, and Father of his Country. In the year 1189, a fleet, composed for the most part of English vessels, but having on board a great number of adventurers of other nations, bound for the Holy Land, entered the river Tagus. They were very kindly received and supplied with all kinds of refreshments by Don Sancho, who took this opportunity of soliciting them to assist him in a design he had formed of attacking the city of Silvas in Algarve, to which they readily assented. Having joined them with a squadron of his own galleys, and marched a body of troops by land, the place was reduced, and the English, according to agreement, were rewarded with the plunder. But in a short time, the Moors from Africa having once more invaded Portugal, the town was several times taken and retaken, until at last Don Sancho, sensible of the difficulties of retaining it, caused it to be demolished. His last enterprise was the reduction of Elvas; soon after which he died, leaving the reputation of being the best economist that ever sat on the throne of Portugal. With the character of being rather liberal than avaricious, he had amassed a treasure of more than seven hundred thousand crowns in ready money, besides fourteen hundred merks of silver, and one hundred of gold plate, which he disposed of some time before his death. He was interred by his own command in the cathedral of Coimbra; and when his body was taken up four hundred years afterwards, that it might be laid in a new tomb, it was found uncorrupted.

Differences with Castille.

The history of Portugal presents scarcely any event of importance till the year 1289; when, in the reign of Don Denis, a difference commenced with Castille, which subsisted for a long period. Frequent reconciliations took place; but these were either of short duration, or never sincere. At length, in the reign of John I., Don Juan of Castille, who had also pretensions to the crown of Portugal, invaded that kingdom at the head of the whole force of his dominions, and with the flower of the Castillian nobility entered the province of Alemtejo. According to the Portuguese historians, he besieged Elvas, but without effect; a disappointment which enraged him to such a degree that he determined the following year to invade Portugal a second time, and lay waste the country before him. Accordingly, having collected an army of thirty thousand men, he invaded Portugal, and took and ruined several places, whilst King John lay inactive, with a small army, waiting for some English succours which he expected. At last he ventured an engagement with the forces which he had, and, notwithstanding the great superiority of the enemy, obtained a complete victory; after which he made an irruption into Castille, and had the good fortune to gain another battle, which fixed him firmly upon the throne of Portugal. The Castillians were obliged to consent to a truce of three years, which was soon afterwards improved into a lasting peace.

The city of Ceuta taken from the Moors.

In 1414, King John undertook an expedition against the Moors in Barbary, where he commanded in person; but before he set out, his queen Philippa, the daughter of John duke of Lancaster, died of grief at the thoughts of his absence. The expedition, however, proved successful, and the city of Ceuta was taken from the Moors almost at the first assault; but scarcely had the king left that country, when the princes of Barbary formed a league for the recovery of the place; and though they were defeated by the young princes of Portugal, whom John again sent into Barbary, yet the trouble of keeping it was so great that some of the king's council were of opinion the town should be demolished. But John, having considered the arguments on both sides, determined to preserve the city; and therefore enlarged and strengthened the fortifications, augmenting his forces there to six thousand foot and two thousand five hundred horse, which he hoped would prove sufficient for repelling the attacks of the Moors.

King John died in 1428, and was succeeded by his eldest son Edward. The latter undertook an expedition against Tangier, in Barbary, but the event proved very unfortunate; the Portuguese being so shut up by the Moors, that, to obtain leave to return to Portugal, they were obliged to give up Ceuta. The king's son, Don Ferdinand, was left as a hostage for the delivery of Ceuta; but, with the utmost cruelty and injustice, the king and council of Portugal constantly refused to deliver up the place. Many preparations indeed were made for recovering the prince by force; but before any thing could be accomplished the king died in 1430, which put an end to all these designs.

Passage to the East Indies discovered.

The war with Barbary continued at intervals, but with little success on the part of the Portuguese; and, till 1497, there is no event of any consequence recorded in the history of Portugal. This year, however, was remarkable for the discovery of the passage to the East Indies by the Cape of Good Hope. The enterprising spirit of the Portuguese had, for a considerable time before, prompted them to undertake voyages along the coast of Africa; yet, when they undertook their first voyage of discovery, it is probable that they had nothing farther in view than to explore those parts of the coast of Africa which lay nearest to their own country. But a spirit of enterprise, when roused and put in motion, is always progressive; and that of the Portuguese, though slow and timid in its first operations, gradually acquired vigour, and prompted them to advance along the western shore of the African continent far beyond the utmost boundary of ancient navigation in that direction. Encouraged by success, they became more adventurous, despised dangers which formerly appalled them, and surmounted difficulties which were once deemed insuperable. When the Portuguese found in the torrid zone, which the ancients had pronounced to be uninhabitable, fertile countries, occupied by numerous nations, and perceived that the continent of Africa, instead of extending in breadth towards the west, according to the opinion of Ptolemy, appeared to contract itself, and to bend eastwards, more extensive prospects opened to their view, and inspired them with hopes of reaching India, by continuing to hold the same course which they had so long pursued.

After several unsuccessful attempts to accomplish what they had in view, a small squadron sailed from the Tagus, under the command of Vasco de Gama, an officer of rank, whose abilities and courage fitted him to conduct this difficult and arduous enterprise. From ignorance, however, of the proper season and route of navigation in that vast ocean through which he had to steer his course, his voyage was long and dangerous. At length he doubled that promontory which had been descried by Diaz, and which, for several years, had been the object of terror and of hope to his countrymen. After a prosperous navigation along the south-east coast of Africa, he arrived at the city of Melinda, and had the satisfaction of discovering there, as well as at other places where he touched, people of a race very different from the rude inhabitants of the western shore of that continent, which alone the Portuguese had hitherto visited. These he found to be so far advanced in civilization and acquaintance with the various arts of life, that they carried on an active commerce, not only with the nations on their own coast, but with remote countries of Asia. Conducted by their pilots, who held a course with which experience had rendered them well acquainted, he sailed across the Indian ocean, and landed at Calicut, on the coast of Malabar, on the 22d of May 1498, ten months and two days after his departure from the port of Lisbon. The samorin or monarch of the country, astonished at this unexpected visit of an unknown people, whose aspect, and arms, and manners, bore no resemblance to those of any of the nations accustomed to frequent his harbours, and who arrived in his dominions by a route hitherto deemed impracticable, received them at first with that fond admiration which is often excited by novelty; but in a short time, from whatever motives, he formed various schemes to cut off Gama and his followers. The Portuguese admiral, however, was not to be overreached by such politics as his. From every danger to which he was exposed, either by the open attacks or secret machinations of the Indians, he extricated himself with singular prudence and dexterity, and at last sailed from Calicut with his ships, loaded not only with the commodities peculiar to that coast, but with many rich productions of the eastern parts of India. He returned to Portugal in two years after his sailing from the Tagus, but with a great loss of men; for out of one hundred and forty-eight persons who sailed with him, only fifty-five returned. The king received him with all possible testimonies of respect and kindness; created him Count of Videgueira; and not only declared him admiral of the Indies, but also made that office hereditary in his family.

The Portuguese entered upon the new career opened to them with activity and ardour, and made exertions, both commercial and military, far beyond what could have been expected from a kingdom of such inconsiderable extent. All these were directed by an intelligent monarch, capable of forming plans of the greatest magnitude with systematic wisdom, and of prosecuting them with unremitting perseverance. The prudence and vigour of his measures, however, would have availed but little without proper instruments to carry them into execution. Happily for Portugal, the discerning eye of Emanuel selected a succession of officers to take the supreme command in India, who, by their enterprising valour, military skill, and political sagacity, accompanied with disinterested integrity, public spirit, and love of their country, have established a title to be ranked amongst the persons most eminent for virtue and abilities in any age or nation. Greater things perhaps were achieved by them than were ever accomplished in so short a time. Within twenty-four years after the voyage of Gama the Portuguese had rendered themselves masters of the city of Malacca, in which the great staple of trade carried on amongst the inhabitants of those regions in Asia which Europeans have distinguished by the general name of the East Indies, was then first established. This conquest secured to them great influence over the interior commerce of India, whilst, at the same time, by their settlements at Goa and Diu, they were enabled to engross the trade of the Malabar coast, and to obstruct greatly the long-established intercourse of Egypt with India by the Red Sea. In every part of the East they were received with respect; in many they had acquired the absolute command. They carried on trade there without rivalry or control; they prescribed to the natives the terms of their mutual intercourse; they often fixed what price they pleased on the goods which they purchased; and they were thus enabled to import from Hindustan, and the regions beyond it, whatever was useful, rare, or agreeable, in greater abundance, and of more various kinds, than had been formerly known in Europe.

The settlement of the Portuguese in India.

Opposition made by the Venetians.

Not satisfied with this ascendant which they had acquired in India, the Portuguese early formed a scheme not less bold than interested, of excluding all other nations from participating in the advantages of commerce with the East; and they accomplished one half of what their ambition had planned. In consequence of this the Venetians soon began to feel that decrease of their own Indian trade which they had foreseen and dreaded. In order to prevent the farther progress of this evil, they incited the soldan of the Mamlukes to fit out a fleet in the Red Sea, and to attack those unexpected invaders of a gainful monopoly, of which he and his predecessors had long enjoyed undisturbed possession. The Portuguese, however, encountered his formidable squadron with undaunted courage, entirely defeated it, and remained masters of the Indian Ocean. They continued their progress in the East almost without obstruction, until they established there a commercial empire; to which, whether we consider its extent, its opulence, the slender power by which it was formed, or the splendour with which the government of it was conducted, there had hitherto been nothing comparable in the history of nations. Emanuel, who laid the foundation of this stupendous fabric, had the satisfaction to see it almost completed. Every part of Europe was supplied by the Portuguese with the productions of the East; and if we except an inconsiderable quantity which the Venetians still continued to receive by the ancient channels of conveyance, our quarter of the globe had no longer any commercial intercourse with India, and the regions of Asia beyond it, except by the Cape of Good Hope.

Inquisition introduced into Portugal.

In September 1522, King Emanuel died of an epidemical fever, and was succeeded by his son John III. The most remarkable transaction of this prince's reign was the introduction of the inquisition into his dominions. This happened in the year 1525, or, as some say, in 1535. A famine happening to cease in a short time after the Holy Office was introduced, the priests persuaded the ignorant multitude that it was a blessing from heaven on account of erecting such a tribunal. It was not long, however, before the bulk of the nation perceived what kind of a blessing the inquisition had conferred. But their discernment came too late; for by that time the inquisitors had acquired such power, that it became equally ineffectual and dangerous to attempt disclosing any of their mysteries.

Solyman the Magnificent. Conduct and policy of the Portuguese.

In the mean time Solyman the Magnificent, the most enlightened monarch of the Ottoman race, observing the rising power and opulence of the Portuguese, attributing it to its proper cause, and eager to supplant them, sent orders to the pasha of Egypt to employ his whole strength against the Christians in the East Indies. The pasha, in obedience to these orders, sailed from the Red Sea with a greater naval force than ever the Mahommedans had employed before, having four thousand Janizaries and sixteen thousand other troops on board. Yet, by the courage and conduct of the Portuguese officers and soldiers, all this mighty armament was defeated, and their East India possessions were saved from the danger which threatened them. In Africa, likewise, the king of Fez was baffled before the town of Safi, whilst fresh quarrels breaking out amongst the native princes, gave great relief to the Christians, who had long been obliged to carry on a defensive war, and had more than once been on the very brink of ruin. For a long time indeed their safety had depended solely on the quarrels of the Moors amongst themselves; for such were the envy and jealousy which reigned amongst the Portuguese, that they could never combine heartily in opposing the common enemy; and therefore, had their enemies united against them, they must certainly have been cut off. But whenever the scheriffs quarrelled with each other, one party was sure to have recourse to the Portuguese, who, by sending them a small supply, secured quiet to themselves, and had the pleasure of seeing their enemies destroy one another. Yet in the end even this had bad consequences. For, on the one hand, it kept up a martial spirit amongst the Moors, and on the other it made them acquainted with the Portuguese discipline; so that after every short interval of repose, they not only found them as much enemies as before, but more formidable than ever. The consequence of all this was, that King John began to apprehend that the conquest of Barbary was impossible, and therefore limited his ambition to keeping those few fortresses which he had already acquired; a necessary and prudent measure, which nevertheless displeased the generality of his subjects.

Brazil.

King John exerted himself greatly in the settlement of Brazil in South America, which he brought into a good state, caused several strong towns to be erected there, and took all possible methods to encourage the conversion of the natives to Christianity. He also introduced many regulations for the welfare and happiness of his subjects. The disputes of the nobility about precedency were frequently attended with disagreeable consequences, which made the king resolve to settle them definitively by established rules; and the principles established by him on this occasion have subsisted ever since, and serve in a great measure to prevent such altercations. He had also other designs in his mind, particularly with regard to the reformation of religious persons of both sexes; but, on a close examination of his affairs, he found that his subjects in general had been so much injured by his leaving their concerns to the inspection of his council, that he was thrown by grief into a kind of apoplexy, from which he never recovered. His death happened in June 1557; and he was succeeded by his son Dom Sebastian III. an infant of three years of age.

Education of the young king.

After the death of King John, the administration remained in the hands of the queen, grandmother of Sebastian, who behaved with great prudence and circumspection. The Moors, however, supposing that under a minority they might be able to dispossess the Christians of such places as they held in Barbary, laid close siege to Masagan. But the queen regent speedily sent succours, and promised such rewards to those who distinguished themselves, that the Moors, although they brought eighty thousand men into the field, were obliged to abandon the enterprise. This was at first magnified as a conspicuous instance of the queen's capacity and wisdom; but, in a short time, the natural aversion which the Portuguese have to the government of women, together with the prejudice they had conceived against her country, as being a Castillian, appeared so plainly, and gave her so much uneasiness, that of her own accord she resigned her authority into the hands of Cardinal Dom Henry, the king's brother. Dom Alexis de Moneses was now appointed the governor to the king, and Gonsales de Gomera and two other priests his preceptors. By these instructors the king's education was totally marred. His governor assiduously inculcated upon his mind that the chief virtue of a king was courage, and that danger was never to be avoided, but always surmounted; whilst his other tutors, instead of instructing him in the true religion, only inspired him with an abhorrence of professed infidels. The consequence was, that he became rash, inconsiderate, and obstinate, displaying all those qualities that conspired to draw upon him the catastrophe which ruined both him and the kingdom.

Sebastian undertakes an expedition against Africa.

After the king had grown up to man's estate, his desire was to distinguish himself against the infidels. He himself intended to conduct an expedition to the East Indies; but the prime minister Alcoçova, who did not choose to attend his monarch to such a distance, substituted Africa in its stead. This expedition the king entered into in the most inconsiderate and absurd manner. He first sent for Dom Antonio, prior of Crato, with some hundreds of soldiers; next he carried his principal courtiers with him from a hunting match, and without equipages; he then sent for the Duke of Aveyro, who brought with him such troops as he could collect on so short a warning; and when all these were assembled, the king spent his time in hunting, and slight excursions against the enemy, without doing any thing of consequence, except exposing his person upon all occasions. At length he returned to Portugal in tempestuous weather, and his unexpected arrival was celebrated with the greatest rejoicings.

The trifling success which had attended the king in this expedition served only to inflame him with a greater desire for another; and from the time of his return he seemed to think on nothing else. He was highly delighted also with an accident which furnished him with a pretence for war, of which, however, he stood in no great need. Muley Hamet, king of Fez and Morocco, had been dispossessed of his dominions by his uncle Muley Moloch. At the beginning of this war Dom Sebastian had offered him the Portuguese troops in Africa, a tender which was rejected with contempt; but now being a fugitive, and having in vain solicited assistance from Philip of Spain, Muley Hamet applied to the king of Portugal; and, that he might the more easily succeed, he caused the fortress of Arzila, which his father had recovered, to be restored to the Portuguese. The king was in rapture at this event, and fancied that his glory would exceed that of all his predecessors. He was, however, dissuaded against engaging in this expedition by all his friends. Philip of Spain, having done everything to dissuade him at a personal conference, sent Francisco Aldana, an old and experienced officer, to Morocco; and, at his return, ordered him to attend Dom Sebastian, in order to give him an account of the state of affairs in that country. This he performed with the greatest fidelity, but without any effect. The queen-dowager and the cardinal united in their endeavours to divert him from this unfortunate enterprise; but he treated them both with so little respect that his grandmother broke her heart; and the cardinal, to show his distaste of the measure, retired to Evora without coming either to court or to council, an example which was followed by many of the nobles. Many of these, however, transmitted remonstrances to the king on the impropriety of his conduct; and Philip sent to him the Duke de Medina Celi to lay before him once more the reasons why he thought his scheme impracticable, and to put him in mind that he had no hand in pushing him upon his destruction, or of concealing from him the dangers into which he seemed determined to plunge himself and his subjects. Lastly, he received a letter on the subject from Muley Moloch himself, in which that prince explained to him his own right to the crown of Fez, and showed that he had only dispossessed a tyrant and a murderer, who had therefore no right to his friendship or assistance. The Moorish prince next assured him that he had no reason to fear either the power or the neighbourhood of the Portuguese; and as a proof of this, as well as a mark of his esteem, he was content to make him a present of some ten miles of arable ground round each of the fortresses he possessed in Africa, viz. Tangier, Ceuta, Masagan, and Arzila. At the same time, he addressed himself to Philip king of Spain, with whom he was on good terms, desiring him to interpose with his nephew Sebastian, that things might yet be adjusted without the effusion of human blood. But the king of Portugal was deaf to all salutary advice; and therefore paid no regard to this letter, nor to the remonstrances of his uncle.

ew expe- tion to frica.

On the 24th of June 1577, he set sail from the bar of Lisbon with a fleet of fifty ships and five galleys, twelve pieces of cannon, and many transports and tenders, making in all near a thousand sail. His troops consisted of nine thousand Portuguese infantry; three thousand Germans; seven hundred Italians, commanded by Sir Thomas Stukeley, an English exile, remarkable for his bravery; two thousand Castillians and three hundred volunteers, commanded by Dom Christoval de Tuvara, master of the horse, a man of courage, but without either conduct or experience. He touched first at Lagos Bay in the kingdom of Algarve, where he remained for four days; and thence he proceeded to Cadiz, where he was magnificently feasted for a week by the Duke de Medina Sidonia, who once more endeavoured to dissuade him from proceeding further in person. But this exhortation proved as fruitless as the rest; and the king having sailed with a strong detachment for Tangier, ordered Dom Diego de Souza, the commander-in-chief, to follow with the remainder of the army.

The troops landed on the coast of Africa without any accident, and joined at Arzila. Here the king was met by the Scheriff Muley Hamet, on whose account he had undertaken the war, who delivered him his son Muley, a boy of twelve years of age, as a hostage, and brought a reinforcement of three hundred Moors. The boy was sent to Masagan under a strong guard; but the father remained in the Portuguese camp. Here it was resolved in a council of war to reduce the town of Larache, but it was disputed whether the troops should proceed thither by land or by sea. Don Sebastian, who espoused the former opinion, finding himself opposed by Muley Hamet, answered him so rudely that he left his presence in disgust; after which the king's opinion prevailed, and the army began its march on the 29th of July. As they proceeded, the king received a letter from the Duke of Alba, requesting him to attempt nothing beyond the taking of the town of Larache. Along with the latter was sent an helmet which had been worn by Charles V.

love- ents and isposi- ons of the rmies.

On the other hand, Muley Moloch, having received intelligence of this formidable invasion, took the field with forty thousand foot and sixty thousand horse, and conducted everything with the greatest prudence, notwithstanding he was so enfeebled by fever that he could not sit upon horseback. Finding reason to suspect that part of his army were desirous of going over to his rival, he proclaimed that such as inclined to join their old master were at liberty to do so. This at once put a stop to the defection, and only a few availed themselves of the liberty which was granted them. Being likewise doubtful of the fidelity of a body of three thousand horse, he sent them to reconnoitre the enemy, by which act of confidence he secured them. Still, however, fearing that his officers might be corrupted by Portuguese gold, he entirely changed the disposition of his army, so that none of his officers commanded the corps to which they had been accustomed, and having new men to deal with, had none in whom they could confide.

Having taken these precautions, he advanced against the Portuguese army with such celerity that he came in sight of them on the 3d of August. On this Dom Sebastian called a council of war, in which many who out of complaisance had declared for this march, were now for returning. They were separated from the enemy by a river, but the Moors being masters of the ford, it was impossible to force them immediately from their post; neither was it practicable for them to wait for a more favourable opportunity, because they had no provisions. The foreign officers, on the contrary, were of opinion that fighting had now become necessary, and a retreat dangerous. This, however, was violently opposed by the scheriff, who saw plainly that they ran a great risk of being defeated, and of losing all, whilst, at the same time, they were not certain of gaining any thing of consequence should they prove victorious; whereas, if they withdrew towards the sea, they might entrench themselves till they were relieved by their fleet; and during this interval, if Muley Moloch should die, he looked upon it as certain that a great part of the army would desert to him, which would render him master not only of the kingdom, but of the fate of the Christians also. When he found that the king was bent upon fighting, he only requested that the engagement might be delayed till four o'clock in the afternoon, that, in case of a defeat, they might have some chance of escaping. But even in this he could not prevail; for the king having disposed everything for a battle the next day, was impatient to begin the onset as soon as it was light.

In the mean time, Muley Moloch was so sensible of the advantages of his situation, that he was inclined to take the whole Portuguese army prisoners; but finding his disease increase to such a degree that he had no hopes of recovery, he came to the resolution to fight, that his antagonist might not avail himself of his death. The disposition of the Christian army was, through the care of some old officers in Don Sebastian's service, regular and correct. The infantry were disposed in three lines; the battalion of volunteers formed the vanguard; the Germans, commanded by Colonel Amberg, and the Italians by Sir Thomas Stukeley, were stationed on the right; the Castillian battalions occupied the left, and the Portuguese were in the centre and rear; the cavalry, consisting of about fifteen hundred men, being partly on the right, under the command of the Duke d'Avegro, to whom the scheriff joined himself with his horse. On the left was the royal standard, with the rest of the cavalry, under the command of the Duke of Barcelos, eldest son of the Duke of Braganza, Dom Antonio, prior of Crato, and several other persons of rank. The king took post at first with the volunteers. Muley Moloch also disposed his troops in three lines. The first consisted of the Andalusian Moors, commanded by three officers who had distinguished themselves in the wars of Granada; the second was composed of renegadoes; and the third consisted of the natives of Africa. They were formed in a crescent, with ten thousand horse on each wing, and the rest in the rear, with orders to extend themselves in such a manner as to encompass the Christian army. Muley Moloch, though extremely weak, was taken out of his litter, and set on horseback, that he might see how his commands had been obeyed; and being perfectly satisfied with the situation of his troops, he directed the signal of battle to be given.

The Christians advanced with the greatest resolution, broke the first line of the Moorish infantry, and disordered the second. On this Muley Moloch drew his sword, and would

The Portuguese army entirely defeated.

have advanced to encourage his troops; but his guards prevented him, on which his emotion of mind became so great that he fell from his horse. One of his guards caught him in his arms, and conveyed him to his litter, where he immediately expired, having only time to lay his finger on his lips by way of enjoining them to conceal his death. But by this time the Moorish cavalry had wheeled quite round, and attacked the Christian army in the rear; upon which the cavalry in the left wing made such a vigorous effort that they broke the Portuguese on the right; and at this time the scheriff, in passing a rivulet, was drowned. In this emergency, the Germans, Italians, and Castillians, performed prodigies; but the Portuguese, according to their own historians, behaved indifferently. Attacked on all sides, however, they were unable to resist; and the whole army, except about fifty men, were killed or taken prisoners. The fate of the king is variously related. According to some, he had two horses killed under him, and then mounted a third. His bravest officers were killed in his defence; after which the Moors surrounding him, seized his person, stripped him of his sword and arms, and secured him. They immediately began to quarrel about the prisoner, upon which one of the generals rode in amongst them, crying, "What, you dogs, when God has given you so glorious a victory, would you cut one another's throats about a prisoner?" At the same time, discharging a blow at Sebastian, he brought the king to the ground, when the rest of the Moors soon despatched him. Others affirm, that one Louis de Brito meeting the king with the standard wrapped round him, Sebastian cried out, "Hold it fast; let us die upon it;" upon which, charging the Moors, he was seized, but rescued by Brito, who was himself taken with the standard and carried to Fez. The latter affirmed, that after he was taken, he saw the king at a distance, and unpursued. Dom Louis de Lima met him afterwards making towards the river; and this is the last account of his being seen alive.

Portugal conquered by Philip of Spain.

Immediately after the battle, Muley Hamet, the brother of Muley Moloch, was proclaimed king by the Moors. The next day, having ordered all the prisoners to be brought before him, the new sovereign gave orders to search for the body of Dom Sebastian. The king's valet-de-chambre brought back a body, which he said was that of his master, but so disfigured with wounds that it could not well be known; and, notwithstanding the most diligent search, this monarch's death could never be properly authenticated. This body, however, was preserved by Muley Hamet, who delivered it up as the body of the unfortunate Dom Sebastian to Philip king of Spain. By the latter it was sent to Ceuta, thence transported to Portugal, and buried amongst his ancestors in the monastery at Belem, with all possible solemnity.

By this disaster, the kingdom of Portugal, from being the most eminent, sunk at once into the lowest rank of the European states. All the young nobility were cut off or carried into slavery, and the kingdom was exhausted of men, money, and reputation; so that Dom Henry, who assumed the government after the death of his brother Dom Sebastian, found himself in a very disagreeable situation. The transactions of his reign were trifling and unimportant; but after the death of the king a great revolution took place. The crown of Portugal was claimed by three different competitors, viz. the Prince of Parma, the Duchess of Braganza, and Philip of Spain. Whatever might have been the merits of their respective claims, the power of Philip quickly decided the contest in his favour. He found his schemes facilitated by the treachery of the regents, who took the most scandalous methods of putting the kingdom into his hands. Under pretence of inspecting the magazines, they withdrew some of the powder, and mixed the rest with sand; they appointed an agent to repair for succours to France, whence they knew that they could not arrive in time; they dissolved the states as soon as they discovered that they were bent upon maintaining the freedom of the nation; and, under a show of confidence, they sent off to distant places such of the nobility as they suspected.

Philip finding everything in his favour, commanded the Duke of Alva to invade Portugal at the head of twenty thousand men. The people, perceiving that they were betrayed, exclaimed against the governors, and placed on the throne Don Antonio, prior of Crato. But his forces being inexperienced, and his own conduct indifferent, he was quickly defeated by the Duke of Alva, and forced to leave the kingdom. On his flight the whole kingdom submitted, together with the garrisons of Barbary, and also the settlements upon the coast of Africa, in Brazil, and in the East Indies. The Madeiras. however, excepting the isle of St Michael, held out for Don Antonio until they were reduced, and the French navy, which came to their assistance, entirely defeated and destroyed.

Terms granted by him to his new subjects.

Philip made his entry into Lisbon as soon as the kingdom had been totally reduced, and endeavoured to conciliate the affections of the people by confirming the terms which he had before offered to the states. These terms were, that he would take a solemn oath to maintain the privileges and liberties of the people; that the states should be assembled within the realm, and nothing proposed in any other states that related to Portugal; that the viceroy or chief governor should be a native, unless the king should give that charge to one of the royal family; that the household should be kept on the same footing; that the post of first president, and all offices, civil, military, and judicial, should be filled by Portuguese, all dignities in the church and in the orders of knighthood confined to the same, the commerce of Ethiopia, Africa, and the Indies, reserved also to them, and to be carried on only by their merchants and vessels; that he would remit all imposts on ecclesiastical revenues; that he would make no grant of any city, town, or jurisdiction royal, to any but Portuguese; that estates resulting from forfeitures should not be united to the domain, but go to the relations of the last possessor, or be given to other Portuguese in recompense of services; that when the king came to Portugal, where he should reside as much as possible, he should not take the houses of private persons for his officers' lodging, but keep to the custom of Portugal; that wherever his majesty resided, he should have an ecclesiastic, a treasurer, a chancellor, two masters of requests, with inferior officers, all of them Portuguese, who should despatch everything relating to the kingdom; that Portugal should ever continue a distinct kingdom, and its revenue be consumed within itself; that all matters of justice should be decided within the realm; that the Portuguese should be admitted to charges in the households of the king and queen of Spain; that all duties on the frontiers should be taken away; and, lastly, that Philip should give three hundred thousand ducats to redeem prisoners, repair cities, and relieve the miseries which the plague and other calamities had brought upon the people. All these conditions, formerly offered and rejected by the Portuguese, the king now confirmed; but although the Duke of Ossuna, by way of security, had promised them a law, that if the king did not adhere to them, the states should be freed from their obedience, and might defend their right by the sword, without incurring the reproach of perjury or the guilt of treason, this he absolutely refused to ratify.

All these concessions, however, failed to answer the purpose; nay, although Philip was to the last degree lavish of honours and employments, the Portuguese were still dissatisfied. This had also an effect which was not foreseen. It weakened the power and absorbed the revenues of the crown; and, by putting it out of the power of any of his successors to be liberal in the same proportion, it raised only a short-lived gratitude in a few, and left a number of malcontents, to which time was continually adding.

reatment
f Dom An-
onio.

Thus Philip, with all his policy and endeavours to please, found his new subjects still more and more disgusted with his government, especially when they found their king treating with the utmost severity all those who had supported Don Antonio. The exiled prince, however, still styled himself, "king of Portugal." At first he retired to France, and there demanded succours for the recovery of his dominions. Here he found so much countenance, that with a fleet of nearly sixty sail, and a considerable body of troops on board, he made an attempt upon Terceira, where his fleet was beaten by the Spaniards, and many prisoners being taken, all the officers and gentlemen were beheaded, and a great number of meaner people hanged. Dom Antonio, however, kept possession of some places, coined money, and performed many other acts of sovereign power; but he was at length constrained to retire, which he did with some difficulty, and returning into France, he passed thence into England, where he was well received; and many fitted out privateers to cruize against the Spaniards under his commission. But after Philip had ruined the naval power of Portugal as well as that of Spain, by equipping the Armada, Queen Elizabeth made no difficulty of owning and assisting Dom Antonio, and even of sending Sir John Norris and Sir Francis Drake with a strong fleet and a considerable army to restore him. Upon this occasion Don Antonio sent his son Don Christoval a hostage to Muley Hamet, king of Fez and Morocco, who was to lend him two hundred thousand ducats. But Philip prevented this by surrendering Arzila; which, with the unseasonable enterprise against Corunna, and the disputes that arose between Norris and Drake, rendered the expedition abortive; so that, except carrying the plague into England, it was attended with no consequences worthy of notice. Dom Antonio remained some time afterwards in England; but finding himself disregarded, he withdrew once more into France, where he fell into great poverty and distress; and having at length died in the sixty-fourth year of his age, his body was buried in the church of the nuns of Ave Maria, with an inscription on his tomb, in which he is styled, "king." He left behind him several children, who, on account of his being a knight of Malta, and having made a vow of chastity at his entrance into the order, were looked upon as illegitimate.

mpostors
retending
o be Dom
ebastian.

But Dom Antonio was not the only pretender to the crown of Portugal. The people, partly from love of their prince, and partly from their hatred to the Castillians, were continually feeding themselves with the hopes that Dom Sebastian would appear and deliver them; and in this respect such a spirit of credulity reigned, that they would probably have taken a negro for Dom Sebastian. This humour induced the son of a tiler at Alcobaça, who had led a profligate life, and at length turned hermit, to give himself out as that prince; and having with him two companions, one of whom styled himself Dom Christoval de Tavora, and the other the bishop of Guarda, they began to collect money, and were in a fair way of creating much disturbance. But the cardinal archduke caused them to be apprehended, and after leading them ignominiously through the streets of Lisbon, he who took the name of Sebastian was sent to the galleys for life, and the pretended bishop was hanged. Not long afterwards, Gonsalo Alvarez, the son of a mason, gave himself out as the same king, and having promised marriage to the daughter of Pedro Alonso, a rich yeoman, whom he created count of Torres Novas, he assembled a body of about eight hundred men, and some blood was spilt before he was apprehended. At length, being clearly proved to be an impostor, this person and his intended father-in-law were publicly hanged and quartered at Lisbon. The punishment, however, instead of extinguishing public credulity, served only to increase it.

remark-
le knave.

About twenty years after the fatal defeat of Sebastian, there appeared at Venice a person who created much more trouble. He assumed the name of Don Sebastian, and gave a very distinct account of the manner in which he had passed his time since that defeat. He affirmed, that he had preserved his life and liberty by hiding himself amongst the slain; that, after wandering in disguise for some time in Africa, he returned with two of his friends into the kingdom of Algarve; that he gave notice of this to the king Don Henry; that finding his life sought, and being unwilling to disturb the peace of the kingdom, he returned again amongst the Moors, and passed freely from one place to another in Barbary, in the habit of a penitent; and that after this he became a hermit in Sicily, but at length resolved to go to Rome, and discover himself to the pope. On the road he was robbed by his domestics, and came almost naked to Venice, where he was known and acknowledged by some Portuguese. Complaint, however, being made to the senate, he was obliged to retire to Padua. But as the governor of that city also ordered him to depart, he, not knowing what to do, returned to Venice, where, at the request of the Spanish ambassador, who charged him not only with being an impostor, but also with many black and atrocious crimes, he was seized, and thrown into prison. He underwent, before a committee of noble and impartial persons, twenty-eight examinations, in which he not only acquitted himself clearly of all the crimes which had been laid to his charge, but entered into so minute a detail of the transactions which had passed between himself and the republic, that the commissioners were perfectly astonished; and, moved by the firmness of his behaviour, his singular modesty, the sobriety of his life, his exemplary piety, and his admirable patience under affliction, they showed no disposition to declare him an impostor. The noise of this was diffused throughout Europe, and the enemies of Spain endeavoured everywhere to give it credit.

The state, however, refused to discuss the point, whether he was or was not an impostor, unless they were requested so to do by some prince or state in alliance with them. Upon this the Prince of Orange sent Dom Christoval, the son of the late Dom Antonio, to make that demand; and at his request an examination was instituted with great solemnity. But no decision followed; only the senate set him at liberty, and ordered him to depart from their dominions in three days. By the advice of his friends, therefore, he proceeded to Padua in the disguise of a monk, and from thence to Florence, where he was arrested by the command of the grand duke, who delivered him up to the viceroy of Naples. He remained several years prisoner in the castle Del Ovo, where he endured incredible hardships. At length he was brought forth, led with infamy through the streets of the city, and declared to be an impostor, who assumed the name of Sebastian; at which words he said gravely, "And so I am." In the same proclamation it was affirmed that he was in truth a Calabrian; but as soon as he heard this he said, "It is false." He was next shipped on board a galley as a slave, and carried to San Lucar, whence, after being for some time confined there, he was transferred to a castle in the heart of Castille, and never heard of more. Some persons were executed at Lisbon for their endeavours to raise an insurrection in his behalf; but it was thought strange policy, or rather a strange want of policy, in the Spaniards, to make this affair so public without proofs; and the attempt to put down the objection, by affirming that he was a magician, justly excited ridicule and contempt.

Bad consequences of the Spanish administration.

The administration of affairs in Portugal, during the reign of Philip, was certainly detrimental to the nation; and yet it does not appear that this proceeded so much from any ill intention in that monarch, as from errors in judgment. His prodigious preparations for the invasion of England impoverished all his European dominions; but it absolutely exhausted Portugal. The pretensions of Dom

Antonio, and the hopes of despoiling their Indian fleets, exposed the Portuguese to the resentment of the English, from which the king wanted power to defend them. Their clamours were not the less loud for their being in some measure without cause. The king, in order to pacify them, borrowed money from the nobility upon the customs, which was the only remedy he had left; and this was attended with fatal consequences. The branches, thus mortgaged, became fixed and hereditary; so that the merchant was oppressed, whilst the king in fact received nothing. This expedient failing, a tax of three per centum was imposed, in the nature of ship-money, for the defence of the coasts and the commerce of the country, and for some years it was properly applied; but it then became a part of the ordinary revenue, and went into the king's exchequer without account. This made way for diverting other appropriated branches; as, for instance, that for the repair of fortifications, the money being strictly levied, whilst the works were suffered to decay and tumble down; and also that for the maintenance of the conquests in Africa, by which the garrisons mouldered away, and the places were lost. Upon the whole, in the space of eighteen years, the nation was visibly impoverished; and yet the government of Philip was so incomparably preferable to that of his immediate successors, that his death was justly regretted, and the Portuguese were taught by experience to confess, that of bad masters he was the best.

Philip III. and Philip IV.

His son Philip, the second of Portugal and the third of Spain, sat twenty years upon the throne before he paid a visit to Portugal, where the people put themselves to a most enormous expense to receive him. He held an assembly of the states, in which his son was sworn as his successor. Having done all that he wanted for himself, he acquired a false idea of the riches of the nation, from the immoderate and foolish display made during his stay at Lisbon; and having shown himself little, and done less, he returned into Spain, where he acted the part of a good king upon his death-bed, in deploring bitterly that he had never thought of acting it before. The reigns of Philip III. and Philip IV. were characterised by a series of bad measures, and worse fortune. All their dominions suffered greatly; Portugal most of all. The loss of Ormus in the east, and of Brazil in the west, together with the shipwreck of a fleet sent to escort one of merchantmen from Goa, brought the nation incredibly low, and encouraged the Conde Duke to hope that they might be entirely crushed. These are the heads only of the transactions of forty years. To enter in any degree into particulars, would only be to point out the breaches made by the Spanish ministers in the conditions granted by Philip; which, with respect to the nation, was the original contract and unalterable constitution of Portugal whilst subject to the monarchs of Castille, but which notwithstanding, they often flagrantly violated.

The Portuguese oppressed by the Spaniards.

The very basis and foundation of their privileges was, that the kingdom should remain separate and independent, and consequently that Lisbon should continue as much its capital as ever. But so little was this observed, that neither promotion nor justice was to be obtained without journeys to Madrid, which was not more the capital of Castille than it was that of Portugal. The general assembly of estates was to be held frequently, and they were only held thrice in the space of sixty years; two of them being held within the first three years. The king was to reside in this realm as often and as long as possible. Philip I., however, was there but once; Philip II. resided only four months; and Philip III. never at all. The household establishment was suppressed during all these reigns. The viceroy was to be a native of Portugal, or a prince or princess of the blood; yet when any of the royal family bore the title, the power was in reality in the hands of a Spaniard. Thus, when the Princess of Mantua was vice-queen, the Marquis de la Puebla was sent to assist her in council, and she could do nothing without his advice. The council of Portugal, which was to be composed entirely of natives, was filled with Castillians, as the garrisons also were, though the contrary had been provided. The presidents of provinces, or corregidors, were to be natives; but, by keeping those offices in his own hands, the king eluded this article. No city, town, or district, was to be given to any except Portuguese; yet the Duke of Lerma had Beja, Serpa, and other parts of the demesnes of the crown, which were formerly appendages of the princes of the blood. None but natives were capable of offices in the courts of justice, in the revenue, in the fleet, or of holding any post civil or military; yet these were given promiscuously to foreigners, or sold to the highest bidder, not excepting the government of castles, cities, and provinces. The natives were so far from having an equal chance in such cases, that no situations in the presidios were ever given to them, and scarcely any in garrisons; and whenever it occurred, in the case of a person of extraordinary merit, whose pretensions could not be rejected, he was either removed, or not allowed to exercise his charge, as happened to the Marquis of Marialva and others. The forms of proceeding, the jurisdiction, the ministers, the secretaries, were all changed in the council of Portugal, being reduced from five to three, then two, and at last to a single person.

A revolution in favour of the Duke of Braganza.

By reason of these and many other grievances too tedious to be enumerated, the detestation of the Spanish government became universal; and in 1640 a revolution took place, in which John duke of Braganza was declared king, by the title of John IV. This revolution, as being determined by the almost unanimous voice of the nation, was attended with very little effusion of blood; neither were all the efforts of the king of Spain able to regain his authority. Several attempts, indeed, were made for this purpose. The first battle was fought in the year 1644, between a Portuguese army of six thousand foot and eleven hundred horse, and a Spanish army of nearly the same number. The latter were entirely defeated; and this contributed greatly to establish the affairs of Portugal on a firm basis. The king carried on a defensive war during the remainder of his life; and after his death, which happened in 1655, the war was renewed with great vigour.

Perilous state of Portugal on his death.

This was what the Spaniards did not expect; for they expressed an indecent joy at his death, hoping that it would be followed by a dissolution of the government. It would not, indeed, be easy to conceive a kingdom left in more perilous circumstances than Portugal was at this time. The king, Dom Alonso Enriquez, was a child not more than thirteen years of age, reputed of unsound constitution both of body and mind; the regency was in a woman, and that woman a Castillian; the nation was involved in a war respecting the title to the crown; and the nobility, some of them secretly disaffected to the reigning family, were almost all of them embarked in feuds and contentions with each other; so that the queen scarcely knew whom to trust or how she should be obeyed. She acted, however, with great vigour and prudence. By marrying her only daughter, the Princess Catherine, to Charles II. king of Great Britain, she procured for Portugal the protection of the English fleets, with reinforcements of some thousands of horse and foot; and at last, in 1665, the war was terminated by the glorious victory of Montesclaros. This decisive action broke the power of the Spaniards, and fixed the fate of the kingdom, though not that of the king of Portugal. Alonso was a prince whose education had been neglected in his youth, who was devoted to vulgar amusements and mean company, and whom the queen for these reasons wished to deprive of the crown, that she might place it on the head of his younger brother Dom Pedro. To accomplish this object, she attempted every method of stern authority and secret artifice; but her endeavours of every kind were vain. The

Portuguese would not consent to set aside the rights of primogeniture, and involve the kingdom in all the miseries attending a disputed succession.

om Alon- obliged resign e throne.

But after the death of the queen-mother, the infant entered into cabals against the king, of a much more dangerous nature than any that she had carried on. Alonso had married the Princess of Nemours; but being impotent, and less handsome than his brother, that lady transferred her affection to Dom Pedro, to whom she lent her assistance to hurl the king from the throne. Alonso was compelled to sign a resignation of the kingdom; and his brother, after governing a few months without any legal authority, was in a meeting of the states unanimously proclaimed regent, and vested with all the powers of royalty. Soon after this revolution, for such it may be called, the marriage of the king and queen was declared null by the chapter of Lisbon; and the regent, by a pontifical dispensation, and with the consent of the states, immediately espoused the lady who had been the wife of his brother. He governed, under the appellation of regent, fifteen years, when, upon the death of the king, he mounted the throne by the title of Dom Pedro II.; and after a long reign, during which he conducted the affairs of the kingdom with great prudence and vigour, he died on the 9th of December 1706.

om John .

Dom John V. succeeded his father; and though he was then little more than seventeen years of age, he acted with such wisdom and resolution, adhered so steadily to the grand alliance formed against France and Spain, and showed so great resources in his own mind, that though he suffered severe losses during the war, he obtained such terms of peace at Utrecht, that Portugal was in all respects a gainer by the treaty. The two crowns of Spain and Portugal were not, however, thoroughly reconciled until the year 1737; but from this period they became every day more united, which gave much satisfaction to some courts, and no umbrage to any. In this situation of things a treaty was concluded in 1750 with the court of Madrid, by which Nova Colonia, on the river Plata, was ceded to his Catholic majesty, to the great regret of the Portuguese, as well on account of the value of that settlement, as because they apprehended that their possession of the Brazils would by this cession be rendered precarious. On the last of July the same year, this monarch, worn out by infirmities, died in the sixty-first year of his age, and the forty-fourth of his reign.

om Jo- eph I.

He was succeeded by his son Joseph I., who ascended the throne of Portugal under very favourable circumstances; but his reign, although short, was marked by great national calamities. The most remarkable event which occurred was the memorable earthquake, which, in November 1755, destroyed one half of the city of Lisbon, and buried thirty thousand people under the ruins. Two hours had scarcely elapsed after this terrible convulsion, when, to aggravate its horrors, flames burst forth from different quarters of the city, and the conflagration raging with terrific violence for three days, Lisbon was completely desolated. The royal family were fortunate enough to escape; but amongst the victims were the Spanish ambassador, and many other persons of distinction. Britain promptly afforded relief to the sufferers; an act of generosity the more honourable to her, as she had every reason to be dissatisfied with the conduct of the king of Portugal. From the commencement of his reign, he had thrown great obstructions in the way of our commerce, evading treaties, and imposing vexatious imposts; and it seemed perfectly clear, that his object was to annihilate the commercial intercourse which had for so many ages subsisted between the two countries. The same spirit of humanity was evinced by Spain; but both nations received an unworthy return, although Britain had most to complain of. The Spaniards were only treated with silent ingratitude, but the English were detested as heretics.

Scarcely had the agitation which these great calamities gave rise to subsided, when Portugal was again thrown into commotion by a pretended conspiracy against the life of the king. No light has yet been thrown upon this dark transaction. The leading parties involved in it, and the ultimate object which they aimed at, are alike unknown. Suspicion fell on various classes of persons, particularly on certain ecclesiastics, who were said to have been incensed at the reform introduced by Dom Joseph; on the creatures of Spain, who aspired to the reunion of the two kingdoms under one sceptre; on the Jesuits, who were represented as indignant at the restriction of their ancient privileges; and on a prince of the royal family. All that is known with certainty is, that the scaffold flowed with noble blood; and that the Jesuits, against whom Pombal had artfully inflamed the passions of the multitude, were stripped of their possessions, whilst their expulsion was decreed by the crown. In fact, the members of the company of Jesus were supposed to be at the bottom of every calamity; whether it was a dispensation of Providence, or an act of human depravity. Even the earthquake was boldly ascribed to them. Pombal had sworn their destruction, and the gross ignorance of the people ministered to his vengeance. Another occurrence of this reign was a rupture with the see of Rome, every servant of the pope being expelled from Portugal, and all intercourse between the two courts suspended for about two years. A more important event was the invasion of the country by Spain. This aggression originated in the refusal of the king to join the alliance of France and Spain against England. War was immediately declared against him, and troops marched to the frontiers of his kingdom. The ally whom he had so long neglected, and even deliberately ill used, was appealed to, and not in vain. Troops, arms, and all necessary munitions of war, arrived from Britain; and although the invaders succeeded in capturing Miranda, Braganza, and Almeida, their triumphs were speedily put a stop to by the combined forces of Britain and Portugal. At the instance of the British cabinet, the Count de Lippe was brought from Germany to assume the command of the whole army. This commander was ably assisted in his operations by General Burgoyne, and they had soon the glory of freeing the country from the Spanish army. The consequence of this triumph was a peace, solicited and obtained by the two hostile courts, now hopless of success, and in apprehension of fresh disasters.

The remainder of this king's reign, extending from the year 1763 to 1777, was occupied by the introduction of measures for social, agricultural, and commercial improvement. He laboured to improve the police and judicial administration, and not without success. He founded schools in the large towns, and improved the system of study in the university of Coimbra. He encouraged agriculture, the fisheries, and trade with the colonies; but in attempting to give a stimulus to home manufactures, by laying such duties on articles of British produce as amounted to an almost total exclusion of them from the Portuguese market, he acted with equal short-sightedness and ingratitude. One monument to his honour, more noble than the statue of bronze which his grateful subjects erected to him in Lisbon during his life-time, remains to be mentioned. This was a decree by which the grandsons of slaves, and all who should be born after the date thereof, were declared free. Although this benefit was confined to Portugal alone, yet, considering the state of matters at the time it was conferred, it must be regarded as an amazing stride in the career of improvement. Joseph I. died in 1777, and was mourned by his people as the best monarch who had swayed the sceptre of Portugal since the days of Philip I. It must, however, be added, that the administration of Pombal threw a false splendour on the reign of this monarch. In principle a freethinker, in profession a reformer, and in character a cruel and cold-blooded tyrant, this man was lauded to the skies by the infidel philosophers of France, because he had expelled the Jesuits from Portugal with every circumstance of barbarity and iniquity. But few or none of his pretended reforms survived his fall, which was hailed with satisfaction by the whole nation; and his name is now remembered only in connection with some of the darkest and foulest deeds recorded in the historical annals of Portugal.

Maria.

Joseph was succeeded by his daughter Maria, whom the necessities of state had induced her father to give in marriage to his own brother. Such revolting connections are unhappily far from rare in the modern history of Portugal. Some attempts were made to exclude her in favour of a nephew, but they proved completely abortive. Though the abilities of this queen were limited, yet she was actuated by good intentions. Her administration was feeble, but upon the whole beneficial. She followed the example of her father in encouraging national industry and reforming the administration of justice. She founded the Academy of Sciences, and introduced into the convents of friars a compulsory form of education, embracing useful literature, philosophy, and the sciences. She likewise endowed several admirable charitable institutions, and went so far in judicial reform as to abolish the law of imprisonment for debt. In short, had her foreign policy resembled her domestic administration, Portugal would have had no reason to complain of her. Maria was forced into a family compact by her powerful neighbours of France and Spain, by which the influence of the latter was strengthened and confirmed, whilst in the same degree that of England was weakened. This alliance was accompanied by a treaty of limits, which fixed the boundaries of Brazil, Paraguay, and Peru, the arrangement being peculiarly favourable to Spain.

In the year 1792 the queen exhibited symptoms of mental alienation, and John Maria Joseph, prince of Brazil, was appointed regent. One of the first acts of his administration was a declaration of war against the French republic, a step which he was induced to take from his connection with England. But commercial distress, the accumulating debt of the country, and the menacing language which France compelled Spain to adopt towards her neighbour, led to a peace in 1797. In 1799 the malady of the queen appearing to be incurable, the prince was confirmed in the regency, with full regal powers; but he made no change in the policy of the government. The same year he was again encouraged to arm against French aggression, in alliance with England and Russia; the victorious career of the revolutionists having received a severe, although, as it proved, only a temporary check. But the glory of the French arms was restored by the genius of Napoleon. After this conqueror had fully confirmed his ascendency, Spain was under the necessity of declaring war against Portugal in the year 1801; but it was soon terminated by the treaty of Badajoz, in consequence of which Portugal was compelled to cede Olivenza to Spain, and likewise to pay a considerable sum of money. After this the prince enjoyed but a mere shadow of power, and at considerable sacrifices maintained a nominal independence, until at last, in 1807, a hostile army under Marshal Junot invaded Portugal; and the house of Braganza was declared by Napoleon to have forfeited the throne. This bold declaration was owing to the prince having refused to seize the English property in his dominions. Having embarked with his family for Brazil, the French general immediately afterwards took possession of his capital, and Portugal sank into the condition of an appendage of France.

General Junot issued a proclamation, in which he declared that justice should be duly administered, tranquillity preserved, and the future happiness of the people solicitously guarded. But these professions were far from satisfying a people of whom the lower classes were dying of absolute want, and two thirds of the merchants were bankrupt. A British force under the Duke of Wellington (then Sir Arthur Wellesley) was promptly despatched to Portugal, where it was joined by a considerable body of national troops, now mustered in the northern provinces, and determined to maintain the struggle for freedom. A junta was immediately established in Oporto, to conduct the government. After some sharp skirmishing between the two armies, the decisive battle of Vimiero,[1] which was fought on the 21st of August 1808, overthrew the power of France in Portugal. The convention of Cintra followed, and the country was evacuated by the French troops. The immediate consequences of this convention, which at the time was severely censured, were highly beneficial. The government displayed an energy which restored subordination, and was felt all over the kingdom. A levy *en masse* of the whole male inhabitants, from fifteen to sixty years of age, was demanded; but it does not appear that the call was responded to with much alacrity. Towards the close of the year 1808, Madrid having surrendered, and the British army under Sir John Moore having been compelled to retreat through the mountains of Galicia to Corunna, the subjugation of Portugal was again resolved upon by the French. The intelligence of the approaching invasion at first spread consternation and dismay throughout Portugal, for it was in no condition to offer any serious resistance to the force of the enemy that menaced the frontiers. But fresh reinforcements arrived from Britain, and General Beresford, who had been appointed commander-in-chief of the armies of Portugal, having established a system of subordination and discipline amongst the troops, confidence was in a great measure restored before a blow could be struck.

Marshal Soult entered the kingdom of Portugal at the head of the French army, after dispersing the Spanish force in Galicia. He was feebly opposed by the Portuguese, who, however, displayed a laudable eagerness to fight. Their commander, General Freyre, was opposed to a regular engagement; but his unruly troops rose in mutiny, and massacred both him and his supporters, under the suspicion of treachery. They were led against the enemy by Baron Eben, a German in the British service, and the battle of Carvalho da Este was fought and lost. Soult then invested Oporto, and although the city had been strongly fortified and garrisoned, it was carried by assault on the 29th of March 1809, after a feeble defence of only three days. Immediately on entering the town, the French soldiery commenced an indiscriminate slaughter of the inhabitants; and although their commander used every effort to repress their fury, the plunder and licentiousness had continued a day and a night before subordination could be restored. The defeat of the Spanish army at Medellin opened an easy road to Lisbon; but the French force was divided into three separate bodies, under three independent commanders, Soult, Victor, and Lapisse, though, from fear of being separately committed, the whole remained inactive, or only engaged in insignificant manœuvres. Each commander appears to have waited for intelligence as to the movements of the others, and by this delay the capital was saved. Such was the situation of affairs when Sir Arthur Wellesley landed at Lisbon on the 23d of April, and assumed the chief command of the armies of England and Portugal. By a series of brilliant manœuvres, the British commander compelled the French to abandon Portugal. But Napoleon being pledged to his people and the world to conquer that country, early in 1810 an army of seventy-two thousand men was assembled in the vicinity of Salamanca, and the command of it intrusted to Marshal Massena. After clearing his way to Portugal, by the capture of several strongly-fortified places, the French general advanced upon Lisbon. But his vigilant enemy had well employed the time afforded him, by preparing a secure asylum for his troops, by which he at once kept his footing in the peninsula, and defended Lisbon against a greatly superior force. This formidable defensive position is celebrated in military annals by the name of the lines of Torres Vedras. The advance of Massena, the battle of Busaco, the stand made at Torres Vedras, the retreat of the French, and their final evacuation of Portugal, will be found described in the article BRITAIN. It is true, that in the subsequent operations of the war, some parts of the kingdom were included in the theatre of hostilities, yet they never extended much beyond the frontiers. During the remainder of the war, however, the troops of Portugal bore an active and creditable part in almost every encounter with the enemy.

---

[1] The operations of the British army in Portugal and Spain having been already narrated at sufficient length in the article BRITAIN, no details will here be given.

John VI.

On the death of Maria, John VI. ascended the throne of Portugal and Brazil. The establishment of the court of Lisbon in an American settlement, though productive of little good to the mother country, led to important results. In the first place, it induced Brazil to withdraw itself from dependence on England; and, secondly, it paved the way for that colony erecting itself into a separate state. But the influence of England in Portugal continued, and the condition of the kingdom for the present remained essentially unchanged by the transference. The peace of Paris, concluded in May 1814, which, it was believed, would place everything on a proper basis, did not realize the expectations of the nation. Spain evaded the restitution of Olivenza, which had been provided for by the congress of Vienna; whilst, at the same time, Portugal was required to restore French Guiana to France. The court of Rio therefore took possession of the Banda Oriental; but an account of these transactions has been given in another part of this work (See BRAZIL.) These circumstances rendered the condition of Portugal far from tranquil. The country felt that the order of things had been inverted, and the parent state had become a dependent on her colony. A conspiracy of a very extensive nature was timeously discovered in the army, and its progress checked; but the spirit which generated it was not extinguished. In short, everything was ripening for a fundamental change in the administration and constitution of government; and the Portuguese people were soon afforded an opportunity of showing their dislike of the absence of the court, and the predominance of English influence. The continual bickerings between the commander of the forces and the regency induced Marshal Beresford to repair to Rio de Janeiro, to obtain fresh instructions, and, it might be, fresh powers, from the king; but during his absence that revolution burst forth which completely changed the whole political aspect of the kingdom.

The first symptoms of this revolution were exhibited at Oporto on the 24th of August 1820, both the citizens and the army acting in concert. The soldiers swore fealty to the king, the cortes, and the constitution which might be adopted, and the civil authorities declared in favour of the measure. A junta of thirteen members was chosen by acclamation; and a declaration was addressed to the nation, stating, that the assembling of the cortes and the adoption of a new constitution were the only means of saving the state. On the 15th of September, the day on which it was usual to celebrate the deliverance of Portugal from France, the regency in Lisbon, fearing to assemble such a multitude of people as generally met on that day, resolved to omit the ceremony. But the troops and the citizens met, and deposed the government; declared for the king, the cortes, and the constitution; and installed a temporary council as a provisional government. Thus a complete revolution was effected, without either violence or bloodshed. The provisional government formed a union with the junta of Oporto on the 1st of October; and one of the earliest acts of this united body was to despatch Count Palmella, the head of the royal regency, to Brazil, with an account of the transactions which had just taken place, and a petition that either the king or the prince royal would return to Europe and assume the sovereignty of Portugal. In the mean while, dissensions of the most inveterate description arose amongst the members of the two juntas. One party, being eager for the immediate adoption of the constitution which had been given to Spain, compelled the supreme junta to declare for, and oblige the troops to take the oath of fealty to, that constitution. But the ascendency of this party was of short duration, and ultimately it was agreed that, for the present, no part of the Spanish constitution should be in force except that which related to the mode of electing the cortes. This was to choose one deputy for every thirty thousand inhabitants. Clergymen, lawyers, and officers, were the sorts of persons who were chiefly elected, few men of wealth or family being chosen. On the 26th of January 1821, the cortes met, and named a regency and ministry, declared the late insurrections legal and necessary, and abolished the inquisition. On the 9th of March, the articles of the new constitution were adopted almost unanimously. By these, freedom of person and property was guaranteed, and the liberty of the press, legal equality, the abolition of privileges, the admission of all citizens to all offices, and the sovereignty of the nation, were secured. One chamber and a conditional royal veto were likewise resolved upon.

John VI. returned from America, leaving his eldest son, Dom Pedro, viceroy or regent of Brazil; but the aged monarch found, on his arrival in Europe, greater troubles than those from which he had fled. He was under the necessity of acceding to certain restrictions on his power, imposed by the cortes, before he was permitted to disembark. On landing, he swore to observe the new constitution, and concurred in all the succeeding acts of the cortes. To add to his disquiet, Dom Pedro accepted the dignity of constitutional Emperor of Brazil, in May 1822, and a complete separation took place between the two countries. The constitution of Portugal was finally completed and sworn to by the king on the 1st of October 1822; and, shortly afterwards, the session of this extraordinary cortes closed. The members of the old cortes occupied several months in reorganizing the different departments of the administration; but measures were rapidly maturing for the total overthrow of the new order of things. After several sanguinary engagements, the insurgents were driven from the northern provinces into Spain, and a Portuguese regency was established at Valladolid in May 1823. At the head of the plot for abolishing the new constitution was the queen, a Spanish Infanta; and several of the nobility and clergy were likewise engaged in it. Everything was now ripe for execution. Dom Miguel violated the promise which he had solemnly given to his father, by becoming the leader of the counter-revolutionists, and inviting the nation to rise under the royal standard against the anarchical policy of the cortes. The greater part of the troops declared for the Infant, and John VI., yielding to the force of circumstances, named a new ministry, and declared the constitution of 1822 null and void. Sixty members of the cortes protested against this proceeding; but the king, a mere puppet in the hands of his son, was borne along by the force of the current, without being able to give any effectual check to its course.

The events which subsequently occurred in Portugal are still too recent to have yet assumed their just historical proportions. The object of the queen and the Infant was to induce the king to resume absolute power; but John VI. firmly declared his resolution not to comply with this request. The counter-revolutionists, however, began to act independently of his authority. The national guards and militia were disarmed, a censorship of the press was established, many of the staunchest constitutionalists were disposed of by imprisonment or expatriation, and the highest offices were conferred on the absolutists. Finally, a junta, with Palmella at its head, was organized, to draw up a constitution adapted to a representative monarchy. The queen and the Infant, with their followers, exerted their whole energies to prevent the establishment of a constitution. Palmella and his coadjutors drew up a constitutional charter. By this act he rendered himself obnoxious both to the queen and Dom Miguel, as well as to the absolutist party; and the king, probably more in compliance with their wishes than from his own conviction that the plan was bad, rejected it. The intrigues of the absolutists still continued. Dom Miguel was appointed commander-in-chief of the army, and, having obtained this office, determined at one blow to extinguish all the hopes of the constitutionalists, and to put an end to the system of moderation, according to which the king continued to act. Upon the 30th of April 1824, Miguel called the troops to arms, and issued proclamations, in which he declared it as his intention to complete the work of the 27th May 1823, and to emancipate the king from the control of free-masons and others by whom he was surrounded. The ministers and other civil officers, to the number of one hundred persons, were on the same day put under arrest; but when the king ascertained what had occurred, he declared that the whole had been done without his orders. As an excuse for his conduct, the Infant said that he had taken these steps for the purpose of frustrating a conspiracy which had been formed against the king's life. On the representations of the foreign ambassadors, the individuals imprisoned were released; and on the 3d of May the king issued a decree, commanding an immediate investigation of the pretended treason. He also pardoned the Infant for his usurpation of the royal name; but this incorrigible person still acted on his own authority, as if he were absolute sovereign, continuing to arrest obnoxious or suspected individuals. John, finding himself in danger of falling a victim to the intrigues of his son, contrived to escape on board of an English vessel which lay in the Tagus. He deprived the Infant of his command, and summoned him into his presence. The prince obeyed, and having confessed his various delinquencies, received the royal pardon, with permission to travel. The king returned on shore, proclaimed an act of amnesty in favour of the adherents of the cortes of 1820, and, reviving the old constitution of the estates, summoned the cortes of Lamego. A new junta was appointed to prepare a constitution; but the convocation of the old cortes was resisted, and conspiracies were formed against the king and his ministers. The latter were themselves far from being unanimous, chiefly in regard to Brazil, so that a new ministry was appointed in January 1825. Portugal and Brazil assumed a hostile attitude, but at length John VI. concluded a treaty with the emperor Dom Pedro I. of Brazil, in which he acknowledged the entire independence of that country, and resigned the sovereignty of it to his son, reserving for himself only the title of emperor. This good-natured monarch, who was incompetent to struggle with the troubles of his age, and the political degeneracy of his nation, died on the 10th of March 1826, having previously appointed his daughter Isabella regent of Portugal.

Isabella for a short time governed Portugal in the name of the emperor of Brazil, Dom Pedro, who was the legitimate successor to both the European and American possessions of the house of Braganza. On the 23d of April 1826 he granted a constitution to Portugal, which established two chambers, and in some other respects resembled the French charter. Not long afterwards, he surrendered Portugal to his daughter, Donna Maria, as an independent queen, on condition of her marrying her uncle, Dom Miguel. The prince at once agreed to this arrangement, but, with his characteristic duplicity, resolved on evading its conditions. The absolutists, of whom he was the recognised chief, were still very strong in the country; and a party was formed, the very object of which was to overthrow the constitution, and proclaim Dom Miguel absolute king of Portugal. The attempt was made, but it proved unsuccessful. A strong British army was landed at Lisbon, and the country, thus overawed, was in some measure restored to tranquillity. Spain, which had secretly fomented the insurrection, was now forced to yield. In July 1827, Dom Miguel was appointed by his brother lieutenant and regent of the kingdom. The prince immediately quitted Vienna and returned to Portugal, taking Paris and London on his way. He was much caressed whilst in England, and pledged himself to abide by the terms required by Pedro. He arrived in Lisbon on the 26th of February 1828, and immediately assumed the administration of the government, at the same time taking the oath to maintain the constitution. But oaths were in his eyes a mere formality of state, involving no moral obligation. He assumed the sceptre as absolute king; changed the ministry to make room for his tools; dissolved the chamber of deputies, which was much too liberal for his views; altered the mode of election; and, in short, restored the reign of absolutism. The recall of the British troops removed another obstacle from his path. He convoked the ancient cortes of Lamego, and was in a fair way of carrying everything before him. But the military in general were unfavourable to his projects. The garrison of Oporto declared for Dom Pedro and the charter; other bodies of troops followed their example; and a corps of six thousand men advanced towards the capital. But they were defeated by a superior force, and the efforts of the constitutionalists were for the present baffled.

The object of Dom Miguel was now to consolidate his power, and get himself proclaimed king. The cortes met, and all who were likely to oppose him having been carefully consigned to dungeons, or driven into exile, this body unanimously declared Dom Miguel lawful king of Portugal and the two Algarves. The pretext by which the cortes endeavoured to vindicate its conduct was, that as Dom Pedro had become a foreigner, he had neither a right to succeed himself, nor to appoint a successor. On the 4th of July 1828, Dom Miguel confirmed the decree of the cortes, and assumed the title, as he had already done the powers, of royalty. The punishment of those implicated in the Oporto insurrection followed as a matter of course. An expedition was likewise sent against the refractory islands, which had refused to acknowledge the usurper; and Madeira and the Azores were, with one exception, reduced. The whole dominions of Portugal now became a scene of terror, distrust, and misery, under the sway of this hypocritical and merciless usurper.

In the meanwhile, Donna Maria had set sail from Brazil for Europe; but on arriving before Gibraltar, she found that, under actual circumstances, it would be injudicious, if not dangerous, to land at Lisbon, and accordingly steered for the English shores. She remained some time in London, and during her stay was entertained as queen of Portugal. In August 1829 she returned to Brazil, in which a revolution suddenly deprived her father of his American empire. Having abdicated a crown which he could no longer retain, in favour of his infant son, the ex-emperor sailed for Europe with his daughter, to assert her claims to the throne of Portugal. Under the title of Duke of Braganza he was hospitably received in England, and instantly set to work in making arrangements for effecting the dethronement of Dom Miguel. The usurper still pursued the same course of oppression, and, not content with confining and despoiling his own countrymen, he extended his outrages to British and French subjects. In the year 1830 it was calculated that forty thousand individuals were under arrest for political causes alone; and that five thousand persons were concealed in hiding-places in different parts of the country. How many had been devoted to destruction by being sent to the fatal shores of Africa, and how many had voluntarily exiled themselves, it is impossible to estimate. The British government demanded redress for the acts of violence committed against its subjects; and, on this being refused, a British fleet entered the Tagus, and terrified the tyrant into compliance. France acted in a similar manner, and with even more success; demanding an indemnity for the expenses incurred by the expedition. Even the United States despatched a fleet to Lisbon to obtain satisfaction for injuries done to American commerce. But these repeated humiliations wrought no change in the policy of Dom Miguel. The petty insurrections which frequently broke out were speedily suppressed by the vigour of the government, or the want of concert in the insurgents; and hence these ebullitions of popular indignation caused him little uneasiness. But his finances were now falling into inextricable confusion. The revenue scarcely sufficing for the household expenses and the maintenance of the troops, the usurper was driven to all manner of expedients to relieve his necessities. The island of Terceira, one of the Azores, resisted his claims; and here a regency was formally installed, with the Marquis of Palmella at its head. From this spot Dom Pedro issued a decree in favour of his daughter Donna Maria, at the same time representing Dom Miguel in his true character, as a rebel and perjured usurper.

Although neither the government of France nor that of England gave open assistance to Dom Pedro, both abstained from opposing any obstacles to his measures of recruiting. Many officers of each nation enlisted in his ranks; and towards the end of December three hundred half-pay officers and volunteers sailed for Belleisle on the coast of France, which had been fixed upon as the place of rendezvous. The intelligence of these preparations, whilst it gave encouragement to the constitutionalists, was productive of great alarm to Dom Miguel, who soon discovered that a considerable portion of his own army was not to be trusted. Lisbon became the scene of anarchy, violence, and bloodshed. A regiment of the line broke out into open mutiny, and, dividing itself into three bodies, marched upon three different points, where other troops were stationed, expecting to be joined by them. But they were sadly disappointed in this expectation. Several bloody conflicts took place, and the insurrection was ultimately suppressed. Many persons were shot for treason, and every dungeon and fortress in the kingdom was filled with suspected persons. Meanwhile the island of St Michael's was captured by a force from Terceira, under Villa Flor, one of the members of the regency. Afraid that Madeira would be the next object of attack, Dom Miguel sent a small armament for its defence; indeed a large one could not well be spared at a time when the preparations of Dom Pedro threatened to bring the contest nearer home. This prince had prosecuted his measures with great activity and perseverance; nevertheless, his means appeared altogether inadequate for the conquest of a kingdom. His levies consisted of a motley group of raw recruits, men of desperate fortunes or suspicious characters, idle persons whose object was plunder, disbanded troops from Brazil, Portuguese refugees, and the regiments which had so successfully maintained the cause of the young queen in the Azores. But a kingdom was at stake, and Pedro resolved to hazard a descent upon Portugal. The expedition sailed from the island of St Michael on the 27th of June 1832. It consisted of two frigates, three corvettes, three armed brigs, and four schooners, besides transports, and a number of gun-boats to cover the landing. An officer who held a commission in the British army undertook the command of the naval department. He had been deprived of his rank as a British officer, but became a Portuguese admiral. The whole army on board did not amount to ten thousand men, scantily provided with artillery, and still more scantily with cavalry.

Dom Miguel made every preparation in his power to repulse the threatened attack. On the 8th of July Dom Pedro appeared before Oporto, landed his troops, and took possession of the town, without the loss of a single man. The advantages likely to result from the capture of the second city in the kingdom need not be pointed out, nor was Dom Miguel ignorant of them. He acted with decision, and immediately menaced Oporto from two points. On the 22d of July an action took place, in which his troops were repulsed, and compelled to fall back; but, on the other hand, Dom Pedro was not in a condition to follow up the victory. Another attempt in a different quarter was with more difficulty repelled; but the most discouraging circumstance for the invaders was the utter disappointment of the hopes they had entertained that the population of the country would rise in their favour, and that the army of Dom Miguel would desert its master.

The operations of the naval squadron were attended with little success. Several partial engagements took place between the fleet of Dom Miguel and that of the young queen under Sartorius; but no advantage was gained on either side. Dom Pedro had continued to fortify Oporto from the period of his landing; whilst Miguel, with equal industry, was increasing his army, the greater part of which lay on the north side of the Douro. On the 8th of September the Miguelites made an attack upon Villa Nova, the suburb of Oporto, which they carried; and the possession of this place enabled them to harass the city with a constant fire both of musketry and artillery. An attempt to recover this position utterly failed; but a convent which formed part of it still held out against all the efforts of the Miguelites. The city began to be seriously injured by the incessant fire which was kept up from Villa Nova, and all attempts to dislodge the Miguelites from their position proved abortive. On the 29th of September Dom Miguel made a general assault upon the works with which Oporto was surrounded; but, after manfully maintaining the contest for seven hours, he was compelled to retreat to his former positions. The commanders of Dom Miguel now changed their tactics. Finding that it was impossible to carry Oporto by storm, they determined to prevent all supplies from reaching the city, by erecting batteries on the Douro, so as to command the bar and channel, and thus prevent all vessels from approaching. They effected their purpose, and Dom Pedro found himself reduced to the greatest difficulties.

The operations of 1833, like those of the preceding year, consisted in partial bombardments across the river, or engagements of detachments, occasionally varied by more regular attacks and sallies to destroy works already erected, or prevent new ones from being raised. The casualties were not great on either side, nor was any permanent change effected in the relative situation of the armies. Dom Pedro began the year by placing at the head of his troops the French general Solignac, whom he had created a marshal. A few months afterwards he had a quarrel with his admiral, Sartorius, which for a time threatened serious consequences; but the naval commander being ultimately removed, his place was supplied by another British officer, Captain, now made Admiral Napier. In a short time the latter inflicted a severe blow on Dom Miguel, by the capture of several of his largest vessels, in as gallant a style as any thing recorded in naval history. In short, the fleet of the usurper was utterly annihilated, and he had now only the land force to look to. Previously to this achievement, a body of queen's troops had landed at another point of the coast, and in a few days the whole of the Algarves declared for Donna Maria. This small army, under the command of Villa Flor, now Duke of Terceira, marched upon Lisbon, and on the way completely routed a greatly superior force. The capital was deserted by the garrison; the inhabitants rose *en masse*, and declared Donna Maria their lawful sovereign; and the Duke of Terceira entering Lisbon in triumph, hoisted the queen's colours on the citadel. Dom Pedro instantly set sail from Oporto to assume the government, and no sooner had the intelligence reached France and England, than both immediately acknowledged Donna Maria as queen of Portugal.

Great preparations were made for the defence of Lisbon against the Miguelite army, 18,000 strong, which, under Marshal Bourmont, an experienced general, was now advancing towards the capital. Several attacks were made on the defences during the rest of the year 1833, but the results were unimportant. The liberation of Lisbon led to the recovery of the Cape de Verd Islands, and immediately afterwards Bonavista proclaimed the queen and the constitutional charter. The political measures of Dom Pedro, after assuming the government at Lisbon, were not looked on with a favourable eye. He confiscated the property of all who had served under Dom Miguel, and was guilty of some other arbitrary acts, which did not tend to strengthen his cause.

The affairs of Dom Miguel now began to wear a very unpromising appearance. His authority, indeed, was recognised over a large tract of country; but his navy, which secured him reinforcements from abroad, was destroyed, and events had taken place in Spain which prevented the government of that country from affording him any assistance. The first military operation of importance which took place in 1834 was the capture of Leiria, an important town between Lisbon and Coimbra, which capitulated to the queen's troops on the 18th of February. A battle was lost by the Miguelites near Almoster, where Saldanha was posted; and towns and provinces began to declare for the queen so rapidly, that the cause of the usurper became desperate. He shut himself up at Santarem with a view of keeping up his communications with the frontiers of Spain, whence he expected aid. But from this very point destruction awaited him. It was a singular coincidence, that in Spain as well as in Portugal, an infant queen was supporting her cause by favouring popular privileges, with an uncle for her rival, as a representative of more despotic principles of government. The cause of the two queens being so far the same, a community of interest led to an alliance, to which the courts of Britain and France became parties. Each was recognised as lawful successor to the throne to which she aspired, and they both agreed to employ their arms jointly against their two rivals. Don Carlos was compelled to fly from Spain into Portugal, and thither he was pursued by a Spanish army, which proved even more fatal to Dom Miguel than to Don Carlos. The Miguelites, seeing all hope lost, rapidly disbanded, and only the miserable remnant of an army remained attached to the usurper. A suspension of arms was agreed to; and on the 26th of May a convention was entered into, by which Miguel formally consented to abandon the country. The terms granted him were, that he should never again set foot either in Portugal or Spain, nor in any way concur in disturbing these kingdoms; that he should leave the country within fifteen days; that he should have a pension of about L.15,000, and be permitted to dispose of his personal property, after restoring the crown jewels and other articles; and, finally, that, by his command, the troops still adhering to his cause should instantly lay down their arms, and the fortresses surrender to the queen. On the 2d of June he embarked for Genoa, where he had no sooner arrived than he issued a declaration, declaring that he had acted under compulsion in relinquishing the throne, and that the transaction was null and void.

The civil war being thus terminated, and the authority of the queen acknowledged all over the kingdom, an extraordinary cortes was assembled on the 14th of August. Without the intervention of this assembly, however, the government had previously adopted legislative measures of great moment. It had declared free trade with all countries; fixed the duties on all foreign imports at fifteen per cent. *ad valorem;* reduced all religious houses and regular orders of monks, incorporating their estates with the national domains; changed the state of the currency, and abolished paper money; and made various other sweeping alterations. The measures were well meant, but they were harsh and despotic notwithstanding. After the meeting of cortes, one of the first proceedings of the legislature was to consider how the executive power should be exercised during the minority of the queen. The regency was ultimately conferred on Dom Pedro, but he did not long enjoy it. He expired on the 22d of September 1834, having, during the latter years of his life, acted a part which the earlier stages of his career gave the world little reason to expect. Previously to this, the queen had set about the formation of a new ministry, in which she united some of the more moderate constitutionalists with the former ministers. Her marriage with the Duke of Leuchtenberg, the son of Eugene Beauharnois, and the brother of Dom Pedro's wife, was soon afterwards resolved upon. A bill to exclude Dom Miguel and his descendants from the throne of Portugal was passed without one dissentient voice. The budget for the year 1834 showed a considerable deficit, and this formed an excuse for treating the British auxiliaries, to whom they owed so much, with the most shameful and disgusting ingratitude.

During the year 1835, Portugal presented a peaceful and even prosperous picture, darkened a little by the intrigues of political parties. The principal object of the cortes was to reduce the public debt, or to convert it into securities which should bear a lower rate of interest than that then paid. The fund which was principally looked to for accomplishing this object was the national property, and measures were adopted for effecting sales thereof. The budget for the year ending 30th June 1836 stated the expected receipts at 8,420,257,408 milreis, and the expenditure at 12,744,161,266, being a revenue of about L.2,200,000, and an expenditure of more than L.3,000,000. No new taxes were, however, imposed to cover the deficit, because it was expected that the expenditure would decrease, whilst the receipts would remain stationary or rise.

Prince Augustus of Leuchtenberg, the husband of the young queen, having arrived in Portugal in the beginning of the year 1835, was appointed commander-in-chief of the Portuguese army, a nomination which gave rise to much contention. But death soon cut short the discussion, for the young prince expired on the 28th of March. The chambers, however, did not allow the queen to indulge long in the sorrows of widowhood. The constitutional system depended greatly on a direct succession to the throne, and before the end of the year the queen's second marriage was arranged. The bridegroom was selected from the house of Saxe-Cobourg (a great nursery for the supply of such wants), and he had the honour to be a nephew of the king of the Belgians.

On the 8th of April 1836, Prince Ferdinand of Saxe-Cobourg arrived at Lisbon, and on the following day was formally united to his royal spouse. Government now became extremely annoyed by the question, whether the king should be appointed to the command of the army, when it turned out that this was one of the special conditions of the marriage treaty. The proceeding proved very unpopular, not only with politicians, but the country, and materially hastened a revolution, in which the ministry and the constitution were shipwrecked together. It does not appear, however, that the government anticipated any serious changes, as the country exhibited no dangerous symptoms of discontent, although a good deal irritated by the appointment which the queen had made. Yet the revolutionary plot must have been arranged beforehand, for even the troops of the line were seduced. On the night of the 9th of September 1836, the drums of the national guards beat to arms, and they were soon joined by the garrisons and many influential civilians. An address to the queen was drawn up, requesting her majesty forthwith to dismiss the ministry, to annul the charter, and to proclaim the constitution of 1820. The queen at first hesitated to yield to force, and to recognise statements as to the alleged jeopardy to which the nation was exposed; but she was ultimately compelled to give way. The political constitution of the 23d of September 1822 was declared to be in vigour: but it was at the same time agreed that it should undergo such modifications as circumstances had rendered necessary. A new ministry was immediately appointed, and Prince Ferdinand was deprived of his military commission. But neither the great body of the people nor the more influential classes showed any indications of accordance with the remodellers of government. Almost all the nobility, the superior clergy, and an immense number of persons holding official situations of greater or of less importance, refused peremptorily to take the oaths to the new constitution. The peers, whose existence as a separate legislative assembly was thus abolished, protested to the queen against the measure, and called for vengeance on those who had compelled her majesty to declare it in force. But this only served to irritate the revolutionists. Not long afterwards a counter-revolution was attempted. Commenced without any well-concerted plan, it was prosecuted without energy, and the results were altogether unimportant. At last negotiations being entered into between the queen and the rebels, it was proposed by the court, first, that the general cortes should be immediately convoked, but that the members should be furnished with special powers to make such alterations in the charter of 1820 as were deemed necessary to secure the liberties of the nation and the prerogatives of the crown; and, secondly, that the Chamber of Peers, as it was instituted before the revolution of the 10th of September, should vote upon these alterations, with the exception of those which might relate to the organization of the chambers. To the latter proposition the rebels refused their assent. They likewise demanded of the queen to dismiss her ministers, and form a new cabinet; and she was under the necessity of complying with their demands. Her majesty, indeed, became partially a prisoner in the hands of the democrats, and many of the most distinguished persons of her court sought refuge in voluntary exile.

The principal events which followed these changes were, the economising of the expenditure, the imposition of a tax for the support of the priesthood, the introduction of a uniform system of duties on vessels sailing from Portuguese harbours, the abolition of the slave-trade, and other measures of more or less moment, which had for their object the pacification of the country and the promotion of the general welfare. During the years 1837 and 1838, some provinces of Portugal were kept in constant terror, and, to a certain extent, ravaged by rebel banditti, whose ostensible object was to excite a rising in favour of Dom Miguel. The most noted of these guerilla chiefs was Remechido, who contrived to muster a formidable gang, and, by his daring exploits, to spread dismay throughout Algarve, the scene of his depredations. A military force was at length sent against him, by which the rebels were completely routed on the 28th of July 1838, and their leader, being taken prisoner, unceremoniously shot.

STATISTICS.

Boundaries and extent.

Portugal, the most westerly kingdom of Europe, lies between 36° 55′ and 42° 13′ of north latitude, and between 6° 15′ and 8° 55′ of longitude west from Greenwich. According to the geographer Ebeling, its length from north to south is 301 geographical miles, and its breadth from east to west is 128 miles. It is bounded on the north and east by the Spanish provinces of Galicia, Valladolid, Salamanca, Estremadura, and Seville, and on the south and west by the Atlantic Ocean. It has the figure of a parallelogram, with its longest side from north to south.

Coast.

Portugal has a coast-line of nearly five hundred miles in length, the only province not washed by the ocean being Tras-os-Montes, and Alemtejo is less so than the remaining four. On the north the coast is low at first, but it afterwards becomes rugged and steep. In Beira it again gets flat, sandy, and marshy; in Estremadura it is in one part steep, and in another almost a dead level, and very insecure; in Alemtejo it is low, being full of rocks and shallows; and although at Cape St Vincent it is high and rocky, as we proceed towards the Spanish frontier the country sinks into low sandy downs. The promontories most worthy of notice are, Mondego in Beira; Carvoeiro de Rocha and Espichel in Estremadura; and San Vincente, Carvoeiro, and Santa Maria, in Algarve. On the low coasts there are inlets of the sea, which afford opportunities for the formation of a number of excellent harbours.

Mountains.

Portugal is only separated from Spain politically, not by natural boundaries or peculiarities. Hence, in all its physical relations it is to be considered as a westerly continuation of that country. The principal chains of mountains are prolongations of those which traverse Spain. In the north, between the Minho and Douro, the country is intersected in various directions by the southerly and westerly procession of the Galician and Asturian mountain ranges, which terminate at the sea in a steep and broken coast. The provinces situated in this quarter are alternating mountain and high table-land, a continuation of the lofty table-land of Old Castille and Leon. The Serra de Montezinho, near the northern frontier, is a very lofty range, on the summits of which snow not unfrequently remains during the whole year. The lofty peak of Gaviarra, however, which forms part of the Serra de Suazo, is crowned with perpetual snow. This range runs parallel with the river Lima to the sea, where it terminates under the name of the Serra de Estrica. On the left bank of the Lima extends the Serra de Gerez, in the province of Entre Minho e Douro, and, passing into Tras-os-Montes, declines towards the Lower Douro, where it bears the name of the Serra de San Catarina. In this last-named province is the Serra de Amarao, on the left bank of the Tamega, and stretching down almost to the Douro. To the east of it is the plateau of Guarda, between two and three thousand feet in height, and which on the north-east is bounded by the Serra de Montezinho. In the province of Beira extends the Serra de Estrella, a continuation of a chain which traverses Leon and Castille. This mountain ridge consists of granite and layers of sandstone. It presents a shattered and savage aspect, is covered with snow during the greater portion of the year, and in its ramifications encloses the river Mondego. Its highest summits are those of Cantaro Delgado and the Malao da Serra. Northwards it declines gently towards the Vouga, and stretches in a westerly direction to the gates of Coimbra under the name of the Serra de Alcoba. The southerly branch runs through the province of Estremadura, to the mouth of the Tagus, forming the granite mountains of Cintra, which terminate in the sea at the Cabo de Roca. To the south of the mouth of the Tagus stretches the Serra de Arabida, an inferior range. Between the Tagus and the Guadiana the country is elevated, but, gradually sinking towards the Spanish province of Estremadura, is bounded on the south by a continuation of the Sierra Morena of Spain, which mountain chain is here penetrated by the river Guadiana. The Serra de Caldeirao, which afterwards bears the name of the Serra de Monchique, a ramification of the gigantic Morena, extends in a westerly direction to the sea, where it terminates in Cape St Vincent, and completely encloses Algarve. This serra only yields in height to that of Estrella, and to those of Suazo and Montezinho. Its loftiest peaks are Foya and Picota.

Portugal is therefore a mountainous country throughout, but its profusion of hills and mountains embosom innumerable beautiful and highly-cultivated valleys, and form several fine tracts of table-land. There are, however, two plains of some extent; one to the south of the Tagus, of which that of Santarem forms a continuation, and one on the mouth of the Vouga.

Rivers.

Portugal receives its principal rivers from Spain. The largest are the Tagus, the Guadiana, the Douro, the Lima, and the Minho. The Tagus originates in the Sierra d'Albaracin, on the borders of Cuença and Aragon, flows at first in a northerly direction, and then turns to the south, but during the most part of its course its general bearing is westerly. After traversing several Spanish provinces, it enters the Portuguese territory near the point where it receives the Sever, separates the provinces of Beira and Alemtejo, and after dividing Portuguese Estremadura into two unequal parts, falls into the Atlantic. It receives the waters collected between two parallel ranges of mountains, flows through a mountainous country, and its current is much broken by rocks and cataracts. Its waters are turbid, and annually overflow and fertilize the extensive plains in the environs of Santarem and Villa Franca. Lower down it forms many marshes of considerable extent, which yield a large revenue. The length of its course is four hundred and fifty miles. It is affected by the tide a considerable distance above Lisbon, but is only navigable to Abrantes. Its width is so great near its mouth as to make it resemble a vast lake or arm of the sea; and at Lisbon it forms one of the finest and safest harbours in the world. The tributaries which it receives on the north are the Elga, the Ponsal, and the Zezere ; and those from the south are the Sever, the Sorraya, erroneously called Zatas in most maps, and the Canha; but none of these are navigable. The rivers worthy of notice which have their source in Portugal are the Cavado, Ave, Vouga, Mondego, Saado, Odemira, Portimao, and Rio Quarteira. The Cavado rises in the Serra de Gerez, and after traversing the province of Minho, discharges itself near Esposenda, being only navigable for seven miles. The Vouga has its source in Beira, and after traversing this province, enters the ocean below Aveira. The Mondego issues in the Estrella, crosses Beira and the plains of Coimbra, and finally joins the ocean near Figueira and Buareos. This is the largest of the rivers belonging exclusively to Portugal, and it is navigable for sixty miles, except in summer, when its waters considerably diminish. Its sands occasionally yield particles of gold. The Saado or Sadao has its source in Alemtejo in the Serra de Monchique, and flows with a north-westerly course towards Estremadura. It becomes navigable from Porto de Rey, and enters the ocean by a large bay to the south of Setubal. The same Serra gives rise to the Odemeira and Portimao, the former being navigable to the town of the same name, and the latter as far up as Silves. The Rio Quarteira has its source in the Serra de Caldeirao, and forms at its mouth the small port which bears its name. These rivers, when swollen by the winter rains, overflow their banks, much to the advantage of the country, for the waters leave a rich deposit behind them. In summer they are very low, and many of the smaller rivers of Portugal are dried up during that season. They are in general much obstructed by rocks and bars of sand at their mouths, by which navigation is greatly impeded.

Lakes and springs.

Portugal possesses no navigable canals worthy of notice. On the coast, especially in Alemtejo and Beira, there are morasses, lakes, and inferior inland seas, none of them being of great circumference. Several mountain lakes on the Serra de Estrella are tepid, throwing up bubbles, without, however, materially troubling the waters, which are of crystal clearness. Portugal is rich in medicinal springs, some of which are used for baths. They consist of gaseous and saline mineral waters, and of sulphureous and chalybeate springs. The most celebrated sulphur and warm baths are the Caldas de Gerez in Minho, the Rainha and the Oeiras in Estremadura, those of Chaves and Anciaes in Tras-os-Montes, of San Pedro do Sul and Penagarcia in Beira, and of Monchique in Algarve. The best chalybeates are at Torro de Moncorvo in Tras-os-Montes, those of Amaranha and Guimaraens in Minho, and of Villas in Estremadura.

Geology and mines.

Granite composes the highest mountains of Portugal. The entire province of Minho, and the northern portion of Tras-os-Montes, are formed of it; and, besides, it is found in many other parts of the kingdom. Schistus rock, lying over the granite, also covers a large portion of the country. It forms the frontier mountains of Algarve, those of moderate height in Alemtejo, those of Beira in the environs of Castello Branco, and the chain which accompanies the course of the Douro. The primitive calcareous formation forms a continuation of the mountains between Lisbon and Coimbra, as the Serra de Lousaa, Porto de Moz, and Monte Junto, with the Serra de Arrabida, and the mountain chain which reaches to Algarve. Coal is met with in this formation near Buareos, mineral coal at Cape Espichel, and sandstone is sometimes found covering it. The rocks near Lisbon and at Cape St Vincent are of the tertiary formation, more or less mingled with trap. When the granitic rocks blend with schistus, it is by layers; and it is connected with the latter by a stratification, resembling micaceous schistus. The calcareous structure is changed in Tras-os-Montes into a true micaceous schistus; and it is only here that mountains of the latter are seen in a pure state.

Tin mines appear to have been wrought by the Carthaginians in this part of the peninsula; and it is affirmed that mines of tin-stone existed in some granitic mountains of Beira. Mines of gold and silver were wrought in this country by the Romans. During the last century lead ores were worked near Mogadouro, in Tras-os-Montes, and in the vicinity of Longroiva, on the banks of the Rio Prisco. In Tras-os-Montes a silver-mine was wrought in the year 1628. Mines of plumbago occur near Mogadouro, and iron-mines in the same country, near Figueira and Torre de Moncorvo. The iron forge of Chapacunha is supplied from them. In Estremadura there are two very old establishments of the same kind, one in the district of Thomar, and the other in that of Figuero dos Vinhos. On the frontier of that province, and of its neighbour Beira, are situated the mines of red oxyde of iron by which they are supplied. Iron indeed is one of the most abundant minerals in the country. The mountains in the neighbourhood of Oporto everywhere give indications of copper and other ores; and at Couna there is a deposit of cinnabar. In Portugal there are also mines of antimony, bismuth, and arsenic. Some of the rivers of this country, as well as those of Spain, are washed for the gold which they contain ; and it is said that in this way large quantities of the precious metal were formerly collected. The river Tagus was anciently celebrated for the particles of gold which were found mingled with its sands; but its greatest riches are now borne on its bosom. Indeed, none of the streams yields a quantity worth much above the labour of collecting it. There is only one gold-mine in Portugal, situated in a place called Adissa, in the district of St Ubes; but its annual produce is a mere trifle, not reaching twenty pounds weight at an average. Two coal-mines exist; one near Figueira, and the other near Oporto. The country abounds with most beautiful marbles, but they are comparatively little wrought, from the expenses required to bring them to market. Precious stones are found in Portugal, and also quarries of limestone, gypsum, slate, freestone, millstone, black agate, together with immense beds of pyrites and marcasites, potters' and porcelain clay, and pits of common salt.

imate
l soil.

Various causes conspire to produce great differences in the climate of Portugal in different situations. The most obvious one is the inequality of the soil; but vicinity to the ocean, and to mountain ranges, which afford shelter from the winds, or expose to the direct influence of the sun, also greatly affect the temperature. The mountain chains in the northern part of the country are very rugged and cold, the limits of perpetual snow being in this latitude under eight thousand feet. This cold region comprises a considerable portion of the provinces of Tras-os-Montes and Beira, and the whole of the northern frontiers of Minho. It is to be observed as a general rule, that the sea-coast of these provinces, as well as that of all the others, is very warm, the heat of summer, however, being tempered by the sea-breezes. The elevated plains and mountains are sterile, and destitute of wood; but the valleys and other low situations have a mild and agreeable climate, and are for the most part very fruitful. A great part of Minho is especially deserving of notice for its delightful climate. Estremadura, on the other hand, is very hot in summer and very cold in winter; but the high land throughout the whole southern portion of Portugal has an exceedingly agreeable temperature, equally removed from excessive heat in summer and severe cold in winter. Algarve alone has an African climate, but the excessive heat is greatly tempered by the sea-breezes. Some striking anomalies occur, such as intense summer heats in elevated situations; but they are to be accounted for from the position and nature of the mountain ranges which environ them, and their distance from the ocean. The warmer parts of Portugal have a short winter and a double spring. The first, which commences in February, is a delightful season. The succeeding months are variable, being in some years hot and dry, and in others cold and rainy. Harvest is gathered in June. Summer commences in the last week of July, and continues till the beginning of September. The heat is then very great, parching up all the vegetation on the plains and sea-coast, so that it is necessary to water plants to preserve them from destruction. But even during this hot season the evenings and nights are fresh and cool, and the table-lands and other elevated parts enjoy a modification of temperature. Rain begins to fall early in October, and the vegetation of spring immediately succeeds to that of autumn. Winter lasts from the end of November till February, but the cold is seldom excessive, except in very elevated situations. In December heavy rains descend, accompanied by violent whirlwinds; it is during this period that the rivers are so liable to overflow their banks. The climate of Portugal, in general, may be pronounced salubrious, particularly along the coasts and on the table-lands. Fevers of various kinds appear to be the diseases most prevalent, but there are disorders peculiar to different localities. Almost all the mountain chains of Portugal show, in extinct and shattered craters, their former volcanic activity; and in many districts, in the country around Lisbon for instance, earthquakes are not unfrequently felt in harvest and winter. The fearful convulsion which destroyed the capital has already been mentioned in the preceding historical sketch. Portugal is rarely visited by violent storms, and thunder is only heard during autumn and winter.

Productions.

From the great differences of level which Portugal presents, it abounds in every variety of vegetable productions. Forests of birch, oak, and chestnut are abundant; and fruit is everywhere plentiful. Orchards are met with at the foot of large mountain chains; and lower down may be found the cork-tree, kermes, fir, lemon, and orange. The olive is widely distributed, and the vine is cultivated to a great extent. In the warmest regions we find the aloe of America and the date of Africa. Figs, raisins, almonds, melons, water-melons, plums, cherries, peaches, apples, pears, and chestnuts, are all objects of attention. Of grains, those chiefly raised are maize, barley, wheat, and rye; rice is likewise an object of attention in some parts. Potatoes and other vegetables are partially cultivated, together with hemp, flax, and cotton. The Flora of Portugal, although abundant in some parts, presents little that is remarkable. None of the plants of France or Spain, and only a few of those of Italy and Sicily, are found. In the cold regions a few plants similar to those in the west of England are met with. In the warmer districts poppies thrive well, and the coasts of Beira and Estremadura, with the low sandy plains of Alemtejo, are adorned with the cistus and many varieties of heath. On the northern mountains is a tree peculiar to them, which is called azerino.

Agriculture.

Portugal is behind almost every nation of Europe in agriculture; and the various improvements which are general elsewhere have here been slowly and but recently introduced. The soil is neither manured nor tilled as it ought to be. The plough is composed of three pieces of wood awkwardly fastened together, and imperfectly aided by the clumsy machinery of wheels. The districts best cultivated are the valleys of the Minho, those of the Oporto wine company of Upper Douro, and some portions of Tras-os-Montes and Beira; the remaining territory remains comparatively uncultivated. Where the soil is properly laboured and attended to, abundant crops of wheat, barley, maize, rice, and rye are produced. But enough is not raised to supply home consumption, about one fifteenth of the quantity used being imported. Artificial meadows are almost unknown, except in Minho. The cultivation of potatoes, however, has rapidly extended over the country, and hemp and flax of excellent quality are raised. But the chief attention of the Portuguese husbandman is directed to the production of those articles which find their most ready vent in foreign countries, or which are raised with the least labour. Of the first sort is their wine, which is produced chiefly in the northern provinces. The quantity usually made is about 80,000 pipes of red, and 60,000 pipes of white. The productions that require but little labour, such as chestnuts, almonds, oranges, lemons, and citrons, are also profusely raised, and, with the onions and garlic, form no small proportion of the aliment of the inhabitants. Olive-trees are plentiful, and the oil expressed from their fruit forms an important article of sustenance; and, though not of a quality or flavour that is relished for the table in foreign countries, it is a considerable article of export.

Animals.

Generally speaking, cattle are not abundant in Portugal; for, with the exception of the grazing lands of the Minho, the Estrella, and Monte Junto, and a few other places, in which a beautiful and large breed of cattle is reared, the feeding is decidedly bad. Very little cheese or butter is made, these articles being mostly imported from England and Holland. Horses are far from being numerous, and they are of a small size, but very active. Mules, however, are of a first-rate breed, and they, in a great measure, compensate the deficiency. Sheep are reared to some extent, and their wool is inferior to none but that of Spain. There are numerous herds of goats, and abundance of swine of a peculiar species. Poultry are plentiful; and bees are bred to some extent. The rearing of silk-worms was once a considerable branch of industry; but the great injury sustained by the mulberry plantations during war has subjected it to many fluctuations. Birds are not numerous; but of wolves, wild cats, wild goats, wild boars, stags, and some other species of large game, there are a few in certain localities. Hares are rare, and rabbits are not so numerous as in Spain. Amphibious reptiles are not common, but vipers and venomous serpents abound in the mountains; the other parts of the country, however, appear to be free from them. There are several species of lizards; the insects of Northern Africa occur on the heaths; the butterflies of the south of France on the sides of the Estrella; and the scarabæi of the north are found on the mountains of Northern Portugal. The rivers are amply stocked with fish, and the coasts literally swarm with them. Pilchards are caught in immense quantities. Another very common fish is the pescada, a species of the gadus. Besides these, the kinds in greatest esteem and abundance are the sea and river eel, the sole, rodovalho, savel, ruivo, safio, cavalla, espada, and others.

Manufactures.

The manufactures of Portugal are comparatively unimportant; but the country has in general been underrated in this respect. No comparison can be instituted between its products of this sort and those of more industrious states; but if, notwithstanding the advantages England enjoys, the Portuguese have been able to compete with the English in different manufactures, it may be concluded that industry cannot be at so very low an ebb as is often asserted. However, almost all the finer fabrics are imported. At Alcobaça and Tomar cottons, at Guarda woollens, and at Guimaraens linens, are manufactured. The best goods that are made in the kingdom, as compared with those of other countries, are the cambrics, shirting and table linens, and sewing threads. Glass is manufactured at Leiria, and silk, paper, and other articles elsewhere; whilst in Lisbon there are manufactories of arms, cordage, hats, chocolate, earthenware, tin, copper, lace, mats, ribbands, soap, silk, cottons, with distilleries, tanneries, sugar refineries, and founderies. The Portuguese display considerable skill in working in gold and silver plate; and their taste in cabinet-work is said to be now much improved. Generally speaking, they manufacture most articles of recognised necessity with more or less skill. But neither the mines nor the fisheries are at all attended to as they ought to be. If the former were wrought, their produce might form important articles of commerce; and if the latter were prosecuted, as much fish might be caught as would render the importation of this article unnecessary.

Commerce.

The separation of Brazil from Portugal, together with the loss of her Indian possessions, have reduced the commerce of this country to a mere fragment of what it once was when her ports were the medium through which much of the produce of the east and of the west passed to other countries. Political events have also tended materially to depress the foreign trade of Portugal. Previously to 1820 it was very considerable, but since that memorable epoch in the annals of the country, it has sunk, comparatively speaking, to nothing. The chief articles of exportation are wines, lemons, oranges, figs, almonds, and other dried fruits; salt, oil, sumach, wool, and corkwood. The chief goods imported are wheat and other grains, dried cod, salted meat, butter, cheese, horses, oxen, mules, and other animals, medicinal and drying drugs, linseed-oil, planks, and other kinds of prepared wood, iron, steel, lead, tin, brass, copper, charcoal, tar and pitch, flax, hemp, and silk. Numerous articles of foreign manufacture were wont to be imported, and afterwards re-exported to foreign possessions; but this trade is of course annihilated, or nearly so.

There is a great deficiency of authentic documents regarding the commerce of Portugal. Those which can be relied on relate to periods too far back to admit of their being taken as evidence of the present state of trade, and those of a more recent date are imperfect. The following is a statement of the quantities of British and Irish produce and manufactures imported into Portugal in the year 1835; the declared value is given:—Apparel, slops, and haberdashery, L.13,938; arms and ammunition, L.1293; bacon and hams, L.1479; beef and pork, L.1454; beer and ale, L.2369; printed books, L.935; brass and copper manufactures, L.10,730; butter and cheese, L.94,052; coals, culm, and cinders, L.1561; cordage, L.165; cotton manufactures, L.796,002; hosiery, lace, and small wares, L.20,998; cotton, twist, and yarn, L.13,338; earthenware of all sorts, L.5171; woollen manufactures, L.350,715; fish, herrings, L.122; glass, L.11,753; hardwares and cutlery, L.31,469; hats, L.1990; iron and steel, L.49,484; lead and shot, L.8118; leather, L.6138; saddlery and harness, L.3212; linen manufactures, L.36,184; machinery and mill-work, L.5346; painters' colours, L.3805; plate, jewellery, and watches, L.1281; silk manufactures, L.19,485; soap and candles, L.482; stationery, L.9376; refined sugar, L.6840; tin, L.410; tin and pewter wares and tin plates, L.4176; woollen and worsted yarn, L.680; salt, L.150; all other articles, L.39,625. The total declared value of the whole was L.1,554,326. This was rather less than the amount of exports to Portugal during 1834, but more than for any preceding year. The goods imported from France in 1835 were, French and foreign merchandise, raw produce, L.42,284; manufactures, L.236,374; French merchandise, raw produce, L.27,247; manufactures, L.195,546. The total amount was L.501,453, about one third of that of Great Britain. The goods sent to the Portuguese dependencies are included. Portugal exported to Great Britain in 1835, wines of Portugal, 4,163,719 gallons; sheep's wool, 680,956 lbs.; bees' wax, eighteen cwts.; brandy, 1084 gallons; 2385 goats' skins; sumach, forty cwts.; raisins, twenty-four cwts.; olive oil, 270 gallons; oranges and lemons, 95,656 packages; figs, 828 cwts.; bark for tanning or dyeing, 1015 cwts.; cork, 59,910 cwts.; wheat 2157 quarters; and a few other articles. During the same year Portugal sent to France, raw materials and manufactures to the value of L.38,805; articles in a state fit for use or for consumption, L.41,425; total amount, L.80,231. But Portugal carries on trade with many other countries besides Great Britain and France. For her own products she receives from the Netherlands grain, cheese, colours, and dye-stuffs; from the north of Germany grain, linen, iron, tin, brass, and other metallic articles, and toys; from Denmark, grain and timber; from Sweden, grain, iron, steel, copper, and tar; from Russia, grain, hemp, flax, canvass, linen, cordage and tackling, timber, tar, tallow, furs, and the like; from Dantzig, grain, hemp, and timber. There is likewise a considerable intercourse with the United States, the foreign colonies of the kingdom, Brazil, and other places; but we have no data from which to estimate the extent and value of the foreign commerce. The internal trade, at the best unimportant, suffers from the want of good roads. Canals there are none, and the few navigable rivers are not so at all times, so that until proper roads are made or canals formed, the inland commerce of Portugal must continue to be very limited.

Government, laws and religion.

The government of Portugal, once of the most absolute kind, is now a limited monarchy. The succession is hereditary, and extends to both sexes. The constitution of the kingdom, a sketch of which was laid before the cortes on the 7th of March 1837, is nearly a verbatim copy of that of 1822, an outline of which has already been given. The exceptions relate to the appointment of the senators, and the separation of the counsellors of state. The mode of election now adopted is the direct instead of the indirect. It is further provided, that no deputy can hold a public situation, and no officer in his district, no bishop in his diocese, nor any priest in his parish, is allowed to be chosen. The king and the royal princes are declared incapable of holding the chief command of the army or navy. The cortes have the right to choose a new dynasty should the reigning family become extinct. If the assembly of the cortes is dissolved, a new one must be called together within thirty days at the latest. The authority of the cortes is so great that the power of the sovereign is little more than nominal. The management of the affairs of the nation belongs to the counsel of state. There are six ministers, one for each of the departments of foreign affairs, the interior, finance, war and the colonies, marine, and justice. There are also boards of trade, of navigation, of agriculture, and of manufactures.

For the administration of justice there are two supreme courts of appeal; one at Lisbon, and the other at Oporto. There is also one for each of the provinces of Estremadura, Alemtejo, Algarve, Minho, Tras-os-Montes, Beira, and one for the comarca of Castello Branco in Beira. A court of cassation has been established in the capital. In criminal cases the proceedings are public; in civil matters the parties have the privilege of appointing an arbitrator, who is chosen from a society belonging to each city. Each of the six districts of the kingdom is divided into comarcas or jurisdictions, which are again subdivided into ciudades, villas, and provincial under-courts of justice, called concelhos, houras, contos, julgados, and behetrias, these being distributed in correiçoes, over which a corregidor presides as head judge, and who has a right to speak in the second instance, or court of judicature. The sub-judges are in individual places *juizes de fora;* but in all civil and criminal cases they speak in the first instance. In large towns the civil and criminal jurisdiction is under two *juizes da fora,* one of whom bears the title of *juiz da civel,* and the other that of *juiz da crime.* There are also in the towns and villages *juizes ordinarios,* or *juizes da paz,* a sort of justices of the peace. The number of persons connected with the administration of justice, those who have seats in courts, as judges, advocates, and others, is very great, and the course of law is tedious and expensive. The standard authority in matters of law and justice is the royal ordinances which Alphonso V. collected, and Emanuel I. printed. When this juridical code is not sufficient, the Roman law is appealed to; and in ecclesiastical matters the canon law is the recognised authority. The religion of the state is the Roman Catholic; but the exercise of all other forms of religion is permitted to foreigners. The supreme head of the clergy is the patriarch of Lisbon, who is always a cardinal. There are fourteen bishops under the archbishops of Braga and Evora, the former bearing the title of primate of the kingdom. The number of ecclesiastics and religious houses was at one time very great. In 1822 there were 132 nunneries, with 2980 nuns, 912 pupils and novices, and 1971 servant-women; and their revenue amounted to 432,189 milreis. The number of monasteries was 346, containing 5830 persons, who enjoyed an income of 784,513 milreis. The regular orders of monks have been reduced, and some other alterations relating to the church have taken place since Balbi published his Statistical Essay on Portugal, from which the above facts are taken; but we have no authentic data from which to draw up a correct statement of the present condition of ecclesiastical matters in Portugal. Religion has shared in the political fluctuations of the times.

Population and division.

The following is a tabular view of the statistics of Portugal for the year 1835. The number of square miles and fire-places in the provinces and districts is given on the authority of official documents. The population has been estimated by multiplying the number of fire-places by four and a half, which is reckoned a fair average number of souls for each hearth.

	German Geographical Square Miles.[1]	Population.	Fire-Places.
In Europe.			
Province of Minho.................	126·	872,406	193,868
Province of Tras-os-Montes.....	191·75	331,213	73,603

Western District of the Azores	38·82	135,000	30,000
District of Madeira.........	18·50	112.500	25,000
District of Cape Verd Islands...	149·	54,000	12,000
	224·32	391,500	87,000
In Africa.			
The settlement on the coast of Guinea........................	19·5	20,000	
The settlement of Angola........	14,750·	376,000	
The settlement of Mozambique	13,500·	286,700	
	28,269·5	576,300	
In Asia.			
Government of Goa	223·	417,900	
Government of Dilli and Timor	85·	120,000	
Government of Macao............	4·5	38,400	
		576.300	

The principal cities and towns having above 10,000 inhabitants are, Lisbon, 250,000; Oporto, 80,000; Elvas, 18,000; Coimbra, 15,200; Setuval, 14,820; Braga, 14,400; Evora, 10,500; Ovar, 10,300. In the colonies, Funchal, 20,000; Villa Nova de Goa, 18,500; Ponta Delgata, 18,000; Soanda de S. Paola, 18,000; Angra, 15,000; Cacheu, 15,000; S. Salvadore, 15,000; Mozambique, 12,340; Macao, 12,000.

The national varieties of the population are, Portuguese, 3,397,050; Free Blacks, 595,000; Gallegos, 50,000; Hindus and Malays, 420,000; Negro Slaves, 20,000; Chinese, 64,800.

The varieties of religion amongst the population are, Catholics, 3,782,050; Brahmins and Buddhists, 400,000; Foiten, 64,800; Fetishes, 400,000.

Instruction.

In the year 1822 the statistics of education in Portugal stood thus. The university of Coimbra, founded in 1279, with six faculties, a preparatory college, sixteen hundred students; eight hundred and eighty-three elementary schools; three hundred and twenty-two Latin, and twenty-one Greek and rhetorical schools, together with twenty-seven for theoretical and moral philosophy. The total number of scholars, exclusive of students, was 31,280. To these are to be added the following establishments; the marine and royal academy at Oporto, which had three hundred and twenty-five scholars; the academy of Lisbon, with about as many pupils; the trades' school at Lisbon, with a hundred and fifty scholars; the Lisbon royal school for engineering, artillery, and drawing, with eighty scholars; and the military school at Luz, near the capital, with two hundred students. At Lisbon there are also a royal college for the nobility, and royal schools for the Arabic language, drawing, and architecture, and another for statuary; also an institution for instruction in copperplate engraving, an academy for teaching music, and some others. Surgery is taught at the university of

---

[1] A German geographical mile is nearly equal to 4¾ths English miles.

Coimbra, and in several royal schools; in St Joseph's hospital in Lisbon; and in hospitals at Oporto, Elvas, and Chaves. The military school for mutual instruction, which the children of citizens are permitted to attend, had two thousand five hundred and sixteen scholars. There are other academies for instruction in science, geography, Portuguese history, navigation, marine affairs, artillery, and fortification; an institution for the encouragement of literature and other branches of knowledge at Lisbon; an academy for history and antiquities at Santarem; and an academy for scientific instruction in the small county-town of Tomar in Santarem. Portugal has seven botanic gardens, but some of them are of a very humble description; twelve museums of natural curiosities, open to the public; twelve collections of coins and other antiquities; eight observatories; a royal library at Lisbon, with eighty thousand volumes; and the university library of Coimbra, with sixty thousand volumes. In the fine arts the Portuguese have made but little advancement. There are comparatively few printing-presses in the country; and book-printing establishments on a respectable scale are only to be met with in Lisbon, Oporto, and Coimbra. Works of fiction, and books for edification in the Catholic faith, constitute half the yearly literary produce of the Portuguese. On account of their poverty, it has been customary to print scientific works at the royal expense. It is difficult to say whether the press be free in Portugal, at least according to our ideas of freedom. Liberty of the press was established by a decree in the year 1823; but the cortes annulled it, and appointed a commission of censorship.

Knights, royal titles, &c.

There are seven orders of knighthood in Portugal, viz. the military order of Christ, established in 1319; the order of San Jago, for civil merit, founded in 1288; the order of Avis, for military merit, established in 1213; the military order of the tower and sword, founded in 1459, and revived in 1805–1808; the order of Villa Vicosa, or the immaculate conception, founded in 1818; the female order of Santa Isabel, established in 1804; and the order of the faith. In 1749, the king of Portugal received from Benedict XIV. the title of *rex fidelissimus;* and his Most Faithful Majesty styles himself "king of Portugal and Algarve, of both sides of the sea in Africa, lord of Guinea, and of the navigation, conquests, and commerce of Æthiopia, Arabia, Persia, and India." The heir to the throne is styled Prince Royal; his eldest son, Prince of Beira; the other royal children are called Infants and Infantas of Portugal. The present Braganza line of princes commenced with John IV. who was proclaimed king of 1640. The national escutcheon is a silver shield, with five smaller blue shields lying crossways. On each of these are five silver pennies, placed so as to form a Saint Andrew's cross. There is a red border containing the armorial bearings of Algrave, which are seven golden castles with blue towers. On the summit of the royal helmet there is a golden dragon; and the shield contains two dragons, each holding a flag, adorned with the emblems of Portugal and Algarve.

Finances.

The revenues of the state arise from the extensive crown-lands, together with the hereditary estates of the house of Braganza, and the possessions of the first three orders of knights, the greater portion of which belongs to the crown. The other sources from which the government income is derived are, the customs, a property-tax levied from citizen and countryman, the tenth part of the amount of all goods sold, the profits of the "cross-bull," the impost on several requisites of life, the excise, the "decimas" or tithes of the clergy, stamps, lotteries, the mint, and others. Since the separation of Brazil from Portugal, and the attempt of Dom Miguel to maintain the sovereignty he had usurped, a great disproportion has taken place between the expenditure and the income; the latter being sometimes not equal to the half of the former. The consequence has been the accumulation of a national debt of enormous magnitude for so poor a country, and which there appears to be no immediate prospect of the government being able to extinguish, or even to lessen. We have no information that can be relied on as to its exact amount at present; but as it was stated to be three hundred and twenty-four millions of francs in the year 1832, we are rather below than above the mark in estimating it now, 1838, at four hundred millions of francs, or sixteen millions sterling. The income, as well as the expenditure, but particularly the former, has been subject to great fluctuations. These, however, are mainly to be attributed to the unsettled state in which the country remained for so long a period. In the year 1827, the income was 46,843,975 francs, and the expenditure was 62,162,363, so that there appeared a deficit of 15,292,388 francs. In 1829 the revenue was only eighteen millions, whilst the expenses amounted to forty millions of francs. The following is the budget for 1837–1838:

Income............ 9,294 cantos, = 55,764,000 francs.
Expenditure......11,214 = 67,284,000 ditto.

Deficit...............1,920 cantos, = 11,520,000 francs.[1]

Army and navy.

According to a decree dated on the 4th of January 1837, the organized army consists of, the infantry, thirty battalions, twenty of which are infantry of the line, and ten jägers, in all 21,560 men; the cavalry, eight regiments, four being lancers and four jägers, in all 3680 men; and the artillery, four regiments, and three batteries for the neighbouring islands, consisting of 2232 men. The combined military force of Portugal, therefore, amounts to 27,472 men; and there is, besides, an army of militia about 27,000 strong.

According to an official document of the year 1835, the naval force consisted of two ships of the line, four frigates, six brigs, eight schooners and cutters, eight gun-boats, eight transports, eight packet-vessels, and two steam-boats, in all forty-six sail.

People and language

The inhabitants of Portugal are generally a robust, yet not an industrious people. They are enterprising and persevering, patient in adverse circumstances, excessively attached to their own religion and customs, and, though temporary circumstances may seem to indicate the contrary, they retain a high sense of loyalty to their monarch, and of submission to their spiritual superiors. The Portugese language is derived from the Latin, of which it contains a great proportion of words, though mixed with many others of Arabic origin. In the construction of its sentences it very much resembles the Castillian; but the pronunciation of the syllables differs considerably, being in general less guttural; and there are many words introduced which seem peculiar to itself, and the derivation of which it is difficult to trace, though probably they are to be found amongst some of the tribes on the coast of Barbary. (R. R. R.)

---

[1] Weimar Almanac for 1838.

PORTUMNA, a small market town, in the county of Galway, Ireland. It is situated within half a-mile of the river Shannon, over which there is a bridge, and consists of a long line of cabins built without any regularity. It possesses a church and a Roman Catholic chapel. It is distant from Dublin 74 miles, and had a population in 1821 of 736, and in 1831 of 1122.

POSEGA, a city of the Sclavonian provinces of the Austrian kingdom of Hungary, the capital of a circle of the same name, which extends over 990 square miles, and comprehends one city, six towns, and 254 villages, with 74,200 inhabitants. The city is on the river Orlgava, and contains 410 houses, with 4220 inhabitants, who grow tobacco and silk. Lat. 45. 21. 30. Long. 17. 37. 25. E.

POSEN, one of the provinces of the kingdom of Prussia. It was formerly a part of Poland, but by the several partitions of that distracted country, and by the treaty of Vienna in the year 1815, has been guaranteed to Prussia. It is bounded on the north by west Prussia, on the east by Russian Poland, on the south by Silesia, and on the west by Brandenburg. It extends in north latitude from 51° 10′ to 53° 27′, and in east longitude from 15° 2′ to 18° 33′, and comprehends 12,836 square miles. It is generally a plain, with few elevations or even undulations. It consists for the most part of a sandy soil, though some of the marshy parts, when drained, form most excellent meadows for fattening cattle, and for the dairy. The chief product of the soil, as well as the chief food of the inhabitants, is rye, of which about ten times as much is grown as of wheat. Barley is to rye as four to ten, and oats as three to ten; thus the rye crops exceed the whole of the other. The agriculture was in a miserable state till the possession of the country was secured to Prussia by the treaty of Vienna, under the tranquillity and security created by which, it has been making surprisingly rapid improvement. Between 1802 and 1815, the stock of cattle had diminished; the cows, sheep, and horses being about one-third less in the latter than in the former year. Since 1815, an augmentation has again taken place, and the stock of that description in 1832, was found to have more than doubled. Many of the marshes had been drained and converted into excellent pasture, especially an extensive tract, by the construction of the Bromberg canal, which has improved the soil and formed a good communication through the Vistula with the Baltic sea. The forests, which cover one-twentieth part of the province, are a considerahle means of occupation, and a source of wealth. There are few manufactures in the province, and those have been mostly introduced by settlers from Germany since 1815. No part of Europe has shewn such an increase in the number of its inhabitants, as the province of Posen, but especially in the government of Bromberg, which is the northern division of it, in the ten years from 1817 to 1826, both years inclusive. By the census of the former years the government of Bromberg contained 261,368 souls, and that of Posen 579,753; and by that of the latter year Bromberg contained 330,235, and Posen 715,712; thus exhibiting an account by which, at the same rate, the population would be doubled in less than thirty-two years. In 1815 the German inhabitants were estimated at 140,000, and the Jews at 48,000, but it is probable their increase has been greater than that of the Poles, who formed the rest of the population. The religion of the Poles is mostly Catholic, that of the Germans chiefly Protestant. The former have a bishop, under the archbishop of Gnesen, with 581 churches, and several monasteries and nunneries, and two ecclesiastical seminaries. The latter have 101 churches, and two public colleges or gymnasiums. The nett revenue furnished by this province to Prussia in 1816, was about L.120,000, one-half arising from the forests, and other national estates, and the remainder from direct taxation. The whole province is divided into the two governments of Posen and Bromberg, and the former is divided into seventeen circles.

Posen, a city, the capital of the Prussian province of the same name. It stands on a plain on the banks of the river Warthe, and is surrounded with walls, beyond which are some extensive suburbs. Having been burned down in 1803, its buildings are in a more modern style than formerly. It contains a cathedral, and twenty-five other Catholic churches, five monasteries, and four nunneries, a Lutheran, Calvinist, and Greek church, an episcopal palace, and theatre, with about 2500 houses, and 28,000 inhabitants. It has but little other trade beyond what arises from being the seat of the provincial government. The manufactures, though increasing and improving, are still insignificant, and mostly in the hands of the Jews, whose numbers in the city amount to near 5000, and who have a synagogue and some schools. Lat. 52. 22. Long. 17. 14. 30. E.

POSIDONIUS, a celebrated Stoic philosopher of Apameia in Syria, was the disciple and successor of Panætius, (Strab. xiv. 655.) The exact date of his birth and death are unknown, but he flourished B. C. 78, and came to Rome B. C. 51. (Suidas.) He resided principally at the island of Rhodes, and his reputation was so high that many of the young Roman nobility attended his lectures. He was visited by Cicero, B. C. 78, (Plut. Cic. 4. Cic. N. D. 1, 3), and by Pompey, B. C. 62. (Plin. vii. and Plut. *Pomp.* 42.) Posidonius went to Rome on an embassy respecting the affairs of the Rhodians, (Plut. Mar. 45), and probably at this time visited Spain, (Strab. xiii. 614), Gaul, (iv. 197), and Liguria, (iii. 165). He lived to the age of eighty-four, (Lucian, Macrob. 20), and was succeeded by his grandson Jason, (Suid.) Cicero (Div. i. 3), alludes to a work of his on divination, in five books; but he was not merely a philosopher, he was also an astronomer and geographer, who is frequently quoted by Strabo. He made an attempt to calculate the circumference of the earth, and also the diameter of the sun. (Strab. ii. 95, 138.) He treated at considerable length the phenomena of tides, and observed that they had diurnal, monthly, and annual periods, like the moon, (138, 174.) The scattered fragments of Posidonius have been collected and published, under the title, *Posidonii Rhodii reliquiæ doctrinæ, collegit atque illustravit J. Bake accedit Vrytlembachii annotatio*, 1810.

POSITION, Centre of. From Archimedes to Doctor Wallis, writers have assumed, that there belongs to every *body* an individual point, where, for most purposes, the whole weight may be conceived to reside; and they have called it the *centre of gravity*. The learned Englishman, however, believed himself the first to accomplish a demonstration from the nature of gravity. (Scholium to Prop. xv. *De Centro Gravitatis.*)

But the same point is admirably connected with other properties and contingencies of the body than its weight; and hence different names have been considered as preferable by many writers, such as *centre of inertia*, &c.

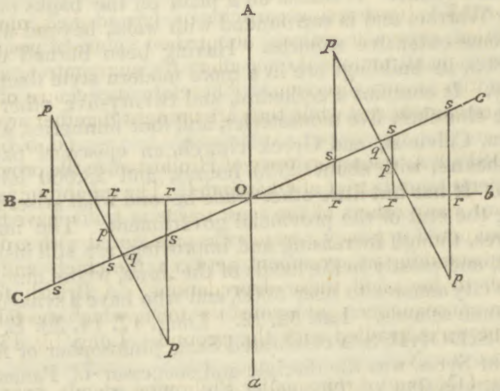
And from viewing a body as composed of physical points, it is found that the relation of this centre to their positions is fertile in some of the most beautiful theorems in the mathematics; whence it has properly received the geometrical designation of the *centre of position.*

We here introduce it in this geometrical character; and shall demonstrate very briefly, but we trust sufficiently, a collection of elegant and most important properties, of which some are virtually proved elsewhere, in a manner more suited to the direct object of their introduction.

If there be any multitude of distinct points in space, it is clear that a plane may move, parallel to any given plane, until the collective distances of the points on one side of it be equal to those on the other.

Let a plane thus situated, relatively to a system of points, be called a plane of equidistance.

Fig. 1.



Suppose two planes of equidistance, A and B, perpendicular to each other. Then, first, we shall find that any plane C which passes through their common section or axis, is also a plane of equidistance to the same system of points. For, let any plane, perpendicular to this axis in O, cut the planes A, B, C, in the straight lines A*a*, B*b*, C*c*, respectively. Then A*a* and B*b* are at right angles. Let a perpendicular from any point of the system meet the plane ABC in *p*. Draw *pq* at right angles to C*c*, and let it be positive when on the same side of the plane C as AO. Also draw *pr* perpendicular to B*b*, and meeting C*c* in *s*; and let *pr* and *rs* be positive when on the same sides of the planes B and C respectively as AO. The triangle *pqs* being given in species, *pq* is as *ps*, that is, as $pr+rs$; so that the sum of the *pq* is as the sum of the *pr* together with that of the *rs*.

But the *pr* are the distances of the points of the system from the plane B, which is a plane of equidistance; and therefore their aggregate is nothing. And again, the *rs* are as the *r*O, which are the distances from the plane A; and, having different signs on the two sides, their aggregate is also nothing. Thus the sum of the *pq* is nothing; and the plane C is a plane of equidistance.

Now let O move along the axis to make ABC a plane of equidistance. Then shall any plane K which passes through O be such a plane.

For let the plane K cut ABC in the line C*c*. The plane ABC, and the plane C, which cuts it perpendicularly in the line C*c*, are planes of equidistance; therefore, by what we have just proved, the plane K which passes through their common axis C*c* is also a plane of equidistance. Thus, to every system of points, there is a point through which every plane is a plane of equidistance. And there cannot be more than one. For if there were two, we might have through them two parallel planes of equidistance, which is manifestly absurd.

This single point has been called the centre of position.

Cor. 1. The difference of the centre of position from any given plane is an average of the distances of the several points of the system; the distances on different sides being distinguished by contrary signs.

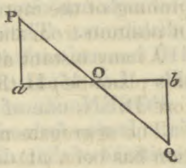
For conceive the parallel plane of equidistance, at the distance D from the given plane. Let the distance of a point of the system from the given plane be denoted by $\text{D}+d$. Then d will vary its sign according as the point of the system and the given plane be on different sides of the plane of equidistance, or on the same side.

Now if there be p points in the system, the aggregate of their distances from the given plane will be $p\text{D}$, together with the aggregate of the d. But the collective d are nothing; so that it will be $p\text{D}$; or D is the average distance.

Cor. 2. If the average distances of the points of a system from three planes, perpendicular or inclined to each other, be given, the centre of position is given. For, by the distances of a point from three such planes, its position in space is given.

Cor. 3. If the centre of position, and the multitude of points in each of two systems be given, the centre of the united systems is found in the straight line joining the given centres at distances from these reciprocally proportional to the multitudes.

Fig. 2.



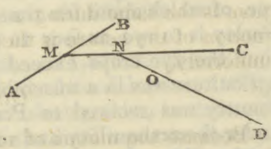
Let P and Q be the centres of position of two systems of p and q points respectively. Let perpendiculars from P and Q meet any plane of equidistance in a and b respectively.

Then $p\,.\,\text{P}a+q\,.\,\text{Q}b$ expresses the collective distances of the points of the united systems from the plane of equidistance, consequently the two terms are of opposite signs and equal magnitude.

And because P*a* and Q*b* are perpendicular to the same plane, they are parallel: so that P*a*, *ab*, *b*Q, are in one plane. Let O be the intersection of PQ and *ab*. Then PO and OQ are as P*a* and Q*b*; and since $p\,.\,\text{P}a=q\,.\,\text{Q}b$, we have also $p\,.\,\text{PO}=q\,.\,\text{QO}$, or $\text{PO} : \text{QO} :: q : p$.

Thus every plane of equidistance passes through the same point O, which is therefore the centre of position.

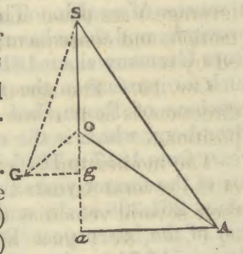
Fig. 3.



Scholium. Hence, if we have any points A, B, C, D, &c., bisecting AB in M, or making $\text{AM}=\frac{1}{2}\text{AB}$; again, making MN to NC as 1 to 2, or $\text{MN}=\frac{1}{3}\text{MC}$; and NO to OD as 1 to 3, or NO== ND, and so on: Then M is the centre of position of the two points A and B; N of the three points A, B, C; O of the four points A, B, C, D, and so on. And as we have proved that there cannot be more than one centre of position to the same system of points, the ultimate point must be the same in whatever order we take the given points into the operation.

Cor. 4. The difference of the squares of the distances of the centre of position from the extremities of any straight line is an average of the difference of the squares of the several points of a system from these extremities.

Fig. 4.



Let SO be the straight line; A a point of a system whose centre of position is G; and A*a* and G*g* perpendicular to the extension of SO. Then $\text{AS}^2-\text{AO}^2=a\text{S}^2-a\text{O}^2=(a\text{S}+a\text{O}).\,\text{OS}$; making *a*S and *a*O negative when measured contrary to the tendency OS.

Hence $\Sigma(\text{AS}^2-\text{AO}^2)=\Sigma(a\text{S}).\,\text{OS}+\Sigma a\text{O}).\text{OS}$. But, if there be p points, $\Sigma(a\text{S})$ is $p.g\text{S}$, and $\Sigma(a\text{O})$ is $p.g\text{O}$. Therefore, $\Sigma(\text{AS}^2-\text{AO}^2)=p.(g\text{S}\times g\text{O}).\text{OS}=p.(\text{GS}^2-\text{GO}^2)$.

Cor. 5. The squares of the distances of any points in space from their centre of position are together less than from any point in the surface of a sphere about this centre, by the square of the radius multiplied by the number of points.

For when G coincides with O, g is also there; and we have $\Sigma(\text{AS}^2-\text{AO}^2)=p.\text{OS}.\text{OS}$, or $p.\text{OS}^2$.

Cor. 6. If A, B, C, &c., express the number of points whose respective centres are in the positions A, B, C; and O be the centre of position of all the points united in one system; then, S being any other point,

$$\text{A.SA}^2+\text{B.SB}+{}^2\text{C.SC}^2=\text{A.OA}^2+\text{B.OB}^2+\text{C.OC}^2+(\text{A}+\text{B}+\text{C})\text{OS}^2.$$

For, by Cor. 4, $\text{A}(\text{SA}^2-\text{OA}^2)+\text{B}(\text{SB}^2-\text{OB}^2)+\text{C}(\text{SC}^2$

$-OC^2$) expresses the excess of the squares of the distances of all the points from S over the squares of their distances from O, which (by the last cor.) is equal to $(A+B+C) . OS^2$.

Cor. 7. In any system of points, the motion of the centre of position, in any given direction, is an average of their several motions in that direction.

For assume a plane perpendicular to the given direction behind all their motions. Let there be p points, and the sum of their distances from the assumed plane, at the beginning of the motion pd. Then the distance of the centre of position from this plane is d.

At any instant afterwards, let their united distances from this plane be pD, that of their centre of position being therefore D.

The aggregate motion of the system in the given direction has been $pD - pd$, or $p(D-d)$, while that of the centre of position has been $D-d$.

Cor. 8. If the several points of a system be uniform as to their motion, the centre of position either rests or moves uniformly.

If it do not rest, whatever be its first tendency, it must persevere in the same. For as it begins without any motion perpendicular to this direction, the aggregate of the motions of the system in any direction perpendicular to this must be nothing, and therefore will continue nothing; so that the centre will never be taken out of its first direction. And as the motion of each point, estimated in this direction, is the same during a given time, the average, or the motion of the centre is the same; so that it traces its path uniformly.

Otherwise.

Because the motion of any point of the system, estimated in three different directions not in the same plane, is uniform in each; that of the centre of position is uniform in these directions, or is nothing. Hence it can have no motion other than uniform in direction and velocity.

Cor. 9. If a body, or system of bodies, be put in motion, and subject to no other disturbance than the action of the parts or bodies upon each other; the centre of position will either rest or move uniformly in a straight line.

For every particle is at first determined to a certain direction and velocity, or put in a condition of uniform motion. And the actions of material particles or bodies upon each other, (whether by impulsion, attraction, impact, or leverage,) are equal and contrary; so that the aggregate motion, and consequently the average motion, is not affected by it.

Cor. 10. The agregate momentum of a system, in any direction, is as if it were all collected into the centre of position.

The momentum in any direction is the united momenta of the several particles. Now, if there be p particles, and their several velocities in a given direction be denoted by v', v'', v''', &c.; these also represent their several momenta; and if we put $pv=v'+v''+v'''+\ldots\ldots$; v is the velocity of the centre of position. Thus the aggregate momentum is as if every particle were in this centre.

Scholium. When the system is connected these parallel momenta compound a force in the given direction, which passes through the centre of position, or centre of gravity; and is equal to the sum of the several forces. So that the impact of the system is as if all were collected in the centre.

Cor. 11. If a body be left to itself in a state of rotation, the axis of rotation will pass through the centre of position.

For when there is rotation, no point out of the axis can either rest or move in a straight line. Therefore the centre of position will be in the axis.

Cor. 12. If attracting particles be left to their mutual attraction, they will coalesce about their centre of position.

For their attractions do not affect the aggregate or average motion in any direction. Therefore the centre of position remains at rest while they are brought together around it. (O. O. O.)

POSITRA, a sea-port town of Hindustan, in the province of Gujerat, and district of Okamindel. The inhabitants, like those of many others of the coast towns in India, have been long addicted to piracy; which was prosecuted with ardour, notwithstanding an agreement between the chiefs and the British to lay aside these depredations. A British force was in consequence sent against the town, which was taken, and the walls levelled with the ground. Long. 69. 17. E. Lat. 22. 23. N.

POSON, one of the smaller Philippine islands, near the west coast of Leyta. Long. 124. 24. E. Lat. 10. 43. N.

POSSESSION ISLAND, in the South Pacific Ocean, discovered by Monsieur Marion in 1772. It is of a round form and mountainous. Long. 41. 40. E. Lat. 46. 30. N. There is another island of this name in the South Pacific Ocean, near the north point of New Holland. It was taken possession of by Captain Cook in the name of Great Britain. Long. 218. 21. E. Lat. 10. 33. N.

POSSESSIVE, in *Grammar*, a term applied to pronouns, which denote the enjoyment or possession of any thing either in particular or in common; as *meus*, mine; *tuus*, thine; *suus*, his own, her own, its own, or their own.

POSTERIOR, a term of relation, implying something behind, or that comes after, another. In this sense it is used in opposition to *prior* and *anterior*.

POSTERN, in fortification, a small gate, usually made in the angle of the flank of a bastion, or in that of the curtain, or near the orillon, and descending into the ditch; by which the garrison can march in and out, unperceived by the enemy, either to relieve the works, or to make sallies against an enemy. The word is also used in general for any private or back door.

POST-HORSE, a rocky inlet in the Eastern seas, near the west coast of the island of Celebes. Long. 119. 18. E. Lat. 5. N.

POSTHUMOUS, a child born after the death of his father, or taken out of the body of a dead mother; and hence frequently applied to the works of an author not published until after his decease.

POSTIL, a name anciently given to a note in the margin of the Bible, and afterwards to one in any other book posterior to the text.

POSTILLIONS, a chain of rocks in the Eastern Seas, about 60 miles in length from north to south. Long. 119. 18. to 119. 54. E. Lat. 6. 15. to 6. 48. S.

POSTLIMINIUM, amongst the Romans, the return of one who had gone to sojourn elsewhere, or had been banished, or taken by an enemy of his own country or state.

POST, a word derived from the Latin *positus*, set or placed. It is used in several different meanings, but all of them referring either immediately or remotely to the primitive sense of *position*. Thus the word post signifies a stake, or piece of timber set upright; a station, particularly a military station; an office or employment; an operation in book-keeping; a conveyance for letters or dispatches; a particular mode of travelling.

POST-OFFICE.

History. It has been usual to trace the origin of posts to a remote antiquity; certain establishments, having something in common with the modern post system, being found to have existed at an early period of the world's history. Herodotus and Xenophon mention that, amongst the ancient Persians, stations were appointed at intervals along the great roads of the empire, where couriers were constantly kept in readiness to convey dispatches and intelligence. Similar institutions, as we learn from Suetonius, were maintained amongst the Romans in the time of Augustus, and such probably existed much earlier.

But although the *name* of the *post* may be traced to this source, (from the Latin word *positus*, whether as applied to the accommodation and means of transport *placed* at intervals for the service of the couriers, or to the couriers themselves, placed or *posted* at the several stations,) such institutions obviously bear but a general resemblance to the post-office of the present times. The couriers were mere state messengers, the communication only to and from the seat of government; nor, as far as appears, was there any regular machinery for the receipt and delivery of letters, so essential to the idea of a modern post establishment.

The posts which were first instituted in the kingdoms of modern Europe, as those by Charlemagne and Louis XI. of France, the Emperor Charles V., and some other sovereigns, differed little, if at all, from those now described. It is indeed probable, that whenever the posts or couriers were appointed to perform their journeys at stated periods (which, as soon as the occasions for employing them became frequent, would be found at once the most economical and effective mode,) such a convenient means of conveying correspondence, though primarily intended only for state purposes, would soon come to be used by individuals. Houses of call, for the receipt and delivery of letters, would in process of time be established by custom, if not by regular appointment; and in this way might grow up the modern post system. The earlier posts instituted in Europe, however, were in general but of temporary duration; their existence being dependent sometimes on occasion, sometimes on the disposition or policy of particular monarchs.

Between the end of the fifteenth and beginning of the seventeenth century, indeed, there were several members, in succession, of the noble family of Taxis in Germany who applied themselves in a remarkable manner to the establishment of posts, and the office of postmaster-general of the empire was eventually conferred on the family as a hereditary fief. As certain posts settled by this family (at a period preceding that in which the modern post system was generally introduced in Europe,) continued permanent, such posts may be considered (unless, indeed, they were at first formed on the modern plan (as affording an instance of transition from the ancient to the modern system. In other cases, however, there is no room for representing the latter as having grown out of any extension, adaptation, or improvement of the former. Thus, in our own country, the insular position of which made our sovereigns less anxious about intelligence from their frontier, nothing of the nature of a public post establishment can be said to have existed, (with an immaterial exception in the reign of Edward IV.) until after the modern form was introduced, the rise of which it is a matter of no difficulty to explain. The conveyance of letters, indeed, is what must inevitably become, in the course of human transactions, as much matter of necessity, as the conveyance of persons or of commodities; and the same circumstances which generate the formation of roads and bridges, and give existence to the trade or occupation of carrier, shipmaster, or innkeeper, must necessarily lead to the employment of the post messenger, under greater or less degrees of system and regularity.

History, more attentive to record the transactions of monarchs, than the steps by which communities effect their advancement and improve their conveniences, furnishes nothing beyond an incidental notice of the modes by which the circulation of correspondence was conducted, before it became matter of state regulation. Of course, however, it is not to be supposed that no such modes existed, or that notices of these are entirely wanting. The conveyance and delivery of letters was often part of the regular occupation of travelling pedlars and others whose business led them to perform stated or frequent journeys. When commerce began to advance, regular conveyances for correspondence were established between some of the principal trading cities, either by the municipal authorities,[1] or by concert of private individuals or associations. A permanent establishment of messengers for the conveyance of letters was attached to the university of Paris, from the beginning of the thirteenth century, and, indeed, was not abolished until the year 1719, long after a general post had been settled in France. Other universities were similarly provided.[2] In some instances powerful and opulent individuals established posts, either as a mercantile speculation, or for the convenience of any district in the prosperity of which they took an interest. But although the conveyance of correspondence was thus brought to some degree of system, or rather prevailed under a variety of systems, even in places where the state authorities had not yet provided any public establishment for this purpose, it is easy to see that communication, especially between more distant places, must have been slow, irregular, and insecure. The advantage and even necessity of having a uniform and legalized system of post conveyance, could not have failed to present itself to the eyes both of subjects and rulers; although it may be a question whether the sovereigns who first established such systems in their dominions were, in general, moved so much by large and enlightened views of public benefit, as by the wish to create, according to the practice so usual in that age, a lucrative trading monopoly in behalf of some of their favourites.

The establishment of the modern post system, then, in regard to the mode of its taking place in some of the principal countries of Europe, is not properly to be viewed as of the nature of a political or civil invention; being merely the assumption, on the part of the state, of the conduct of a particular department of human affairs, which had grown up with the progress of society, but could no longer be competently managed by individuals, whether acting severally or in concert. And accordingly, in acts and ordinances relative to posts, there is not so much in the shape of *offer* of a new species of accommodation, as of *prohibition* against procuring the same accommodation by any other than the offered means.

---

[1] Kennedy, in his annals of Aberdeen, mentions that the magistrates of that city, in the year 1590, appointed a person to convey their dispatches to and from Edinburgh and other places of royal residence. This functionary bore the style of *council post*, and was arrayed in a garment of blue cloth with the town's armorial bearings in silver upon the sleeve. Vol. i. p. 262.

[2] In the act of Queen Anne there is a special clause, permitting letters to be sent to and from the universities of Oxford and Cambridge, "in manner as heretofore hath been used, anything herein to the contrary notwithstanding." The privilege has since ceased to exist.

The notices we possess of the early history of the British post-office, are but meagre and indistinct. What they amount to may be stated as follows. There was a chief postmaster of England in the reign of Elizabeth, if not earlier, Randolph having that title assigned him by Camden (1581); but his duties, of which that author takes no notice, probably related but partially, if at all, to the conveyance of correspondence.[1] James I. appointed a postmaster to take charge of the conveyance of letters to and from *foreign parts;* and different persons are named as successively enjoying this office during his reign and that of his son Charles. In 1635 Charles established a letter office for England and Scotland, which may properly be regarded as the origin of the British post-office. The persons to whose management it was committed, were directed to establish, within a limited time, a post from London to Edinburgh, one to Westchester and Holyhead, and another to Plymouth and Exeter; and the journey from London to the termination of each of these lines and back, was appointed to be performed in six days. Bye-posts were ordered to be established, and other principal lines opened up as occasion might arise; and conveyance of letters otherwise than by post was now prohibited within the kingdom, as it had formerly been between the kingdom and places abroad.[2]

In the year 1642, a committee of the House of Commons was appointed to report on certain matters connected with the post-office; and the subject continued afterwards, at intervals, to engage the attention of the House. In 1644, Mr. Edmund Prideaux, who afterwards held the office of attorney-general to the commonwealth, and who had been chairman of the committee of 1642, was elected postmaster-general by resolution of both Houses of Parliament; "in the execution of which office," says Blackstone, "he first established a weekly conveyance of letters into all parts of the nation, thereby saving to the public the charge of maintaining postmasters to the amount of L.7000 per annum."[3] This has been interpreted to mean (whether correctly or not) that the charges of the post-office previously to the improvement effected by Prideaux, exceeded its income by the sum mentioned.[4] Be this as it may, there seems to have been, from the period of these improvements, a considerable profit realised from the posts. Whether from a desire to share in this profit, or for other reasons, the Common Council of London, in the year 1649, set about establishing a separate post-office; an attempt, however, which was promptly put down by a resolution of the House of Commons, declaring that "the office of postmaster is and ought to be in the sole power and disposal of Parliament."

It appears likely, that, originally, any surplus revenue which might be obtained from the posts, was allowed to belong to the postmaster, and even that the charges for postage were fixed by him, although subsequently regulated otherwise. Thus, the proclamation of Charles I. in 1632,[5] forbidding the conveyance of letters abroad otherwise than by the post, refers to the act of his father, by which the post to foreign parts was first established; and narrates, that that act gave to the postmasters "power to take moderate salaries," meaning, it might be supposed, to charge such rates as would afford moderate salaries; and a little later, in regard to the case of Wytherings, from whom the office of postmaster had been sequestrated by proclamation in 1640,[6] we find the Commons in 1642 declaring the sequestration a grievance and illegal, and "that Mr. Wytherings ought to be restored into the possession of his place as postmaster for foreign parts, and to the mean profits received since he was out of possession, deducting the reasonable and usual charge of execution."[7] At a later period, commencing probably about the time when Prideaux held the office of postmaster, it was the custom to farm the revenues of the post-office.[8]

The post rates first established were twopence for a single letter for a distance under 80 miles, fourpence from 80 to 140, and sixpence above 140. About the year 1654, they were fixed at twopence for 80 miles, and threepence for a greater distance.

Under the authority of the Protector and his Parliament, some material changes were again made in regard to the management of the post-office in 1657, by which it was brought nearer to the model under which it has more latterly subsisted. An advantage held forth in an ordinance[9] passed on this occasion, as one that was to be derived from the establishment of posts, is worth noticing, namely, that "they will be the best means to discover and prevent many dangerous and wicked designs against the commonwealth." Possibly a hint from Charles, some twenty years before, as to making the post-office afford this sort of convenience, had not been very well taken. It does not appear, however, that either at this or any subsequent time, the secrecy of correspondence passing through the British post-office, was ever violated to serve the purposes of government.[10]

The arrangements made in 1657 were confirmed, and some further improvements effected, at the Restoration.[11] In 1663, the post-office revenues were assigned to the Duke of York and his heirs male,[12] and again settled, after his accession to the throne, on the king and his successors, thus becoming part of the hereditary revenues of the crown. From this time nothing of importance seems to have occurred in the history of the post-office, until the year 1710, when was passed the statute 9 Anne, ch. 10, which may be called the charter of the British post-office.

In the system of posts established by Charles I. in 1635, provision was made for the conveyance of letters between England and Scotland, but the royal ordinance makes no mention of an *internal* post for the latter kingdom. The postage between the two capitals was then eightpence; in the time of Cromwell it was fourpence. After the Restoration, the postage to Berwick was fixed at threepence. In the latter part of this century, however, there was a postmaster-general in Scotland, and posts on some of the principal lines of road. In 1667, a post was established to pass between Edinburgh and Aberdeen twice a-week, and one about the sametime, between Edinburgh and Inverness once a-week.[1] Somewhat earlier, (in 1662) a post was established between Ireland and Scotland, and the privy council gave Robert Main, then postmaster-general, an allowance of L.200 sterling, to build a packet boat for conveying the mails between Portpatrick and Donaghadee. The postage to Ireland was sixpence. But whatever was effected in these respects in Scotland, seems to have been entirely by the authority of the local executive, or the magistrates of the principal towns; the first legislative act appointing an internal post in Scotland, being that of the 20th of the 5th Session of the 1st Parliament of William III., passed at Edinburgh in 1695. The preamble of this act embodies the statement that, "for the maintenance of mutual correspondence, and preventing of many inconveniences that happen by private posts, several public post-offices have been heretofore erected for carrying and receiving letters by posts, to and from most parts and places of this kingdom." This act, as also that of the 12th Charles II., was repealed (unless so far as re-enacted) by the statute of Anne above referred to.

---

[1] The name of *posts*, as already observed, had its origin in relation to an arrangement of *travelling stations*, a relation which it continued to preserve; and before the establishment of *letter* offices, the *postmaster* (a use of the term not yet obsolete), was the person who provided the means of conveyance from one station to another. The necessity of regulation and superintendence in regard to an office of this kind, led to the appointment of a *postmaster-general*, to whom such superintendence was committed. For some time after the establishment of letter-offices, the duties of postmaster, in the earlier and later meaning of the term, were conjoined.

[10] It is implied by an *exception* in the declaration made by every post-officer at his entrance into office, that a letter may be opened by warrant of a Secretary of State.

[11] 12th Charles II. c. 35.

[12] 15th Charles II. c. 14.

The act of Queen Anne established a general post-office for, and throughout the kingdom of Great Britain and Ireland, and the colonies in North America and the West Indies, with one master of such office, who was to bear the name and style of her Majesty's postmaster-general. The postmaster-general was empowered to keep one chief letter-office in Edinburgh, one in Dublin, one in New York, and others in the West Indies. In the year 1784, however, about which time there prevailed in Ireland a remarkable jealousy of any assumption of superiority on the part of Britain, an act was passed by the Irish parliament, by which, as well as by certain corresponding acts[2] on the part of the British legislature, the Irish post-office was withdrawn from the government of the British postmaster-general, and placed under an independent officer styled "his Majesty's postmaster-general for Ireland;" but the two offices were, agreeably to the recommendation of the commissioners of revenue inquiry, again consolidated by an act passed in 1831;[3] and at the same time the office of deputy postmaster-general of Scotland was abolished. The whole affairs relating to the post-office throughout the kingdom, were thus put under the direct management of the London board; but the secretaries at Edinburgh and Dublin are still the organs of communication with the country offices, and exercise a general administrative superintendence in their respective divisions of the kingdom.

During the period for which an account has now been given of what may be called the *constitutional* history of the post-office, a very great increase has, as may be supposed, taken place, in the speed of conveyance, and the extent of the communications maintained.

For a considerable time after the first establishment of the post-office, there were no relays of post-boys or horses at different stages; one man and horse accomplishing the whole ride, and taking the necessary rests by the way. The post between Edinburgh and Aberdeen stopped one night at Dundee, and another at Montrose. This system continued in Scotland till about the middle of the last century. Until 1763, the communication between London and Edinburgh was only three times a week; but in that year it was made to be five times a week. At first, the mail was 85 hours in travelling from London to Edinburgh, and 131 hours in returning. In 1757, the time was shortened to 82 hours in the one case, and 85 in the other. Latterly, the journey has been performed by the mail coach, in 42 and 45 hours, the 42 being farther reduced, by the use of the curricle from Morpeth, now discontinued, to 40. Mails are at present conveyed partially by railway, from London to Edinburgh in 33 hours, and from Edinburgh to London in 36.

Until the year 1788, there was no direct mail from London to Glasgow. Previously to that period, the course of post had been five days, the letters being sent round by Edinburgh; and as no mails were dispatched from the latter city upon Sunday, there was in consequence one arrival the less at Glasgow each week. Dr. Cleland[4] tells, that, when a direct mail conveyance was first established (a little before the time now spoken of) from London to Carlisle, the mail for Glasgow, that otherwise would have been the one delayed on Sunday at Edinburgh, was transmitted through Carlisle to Glasgow in four days; notwithstanding which the mails of the other days were allowed for a year to be carried round by Edinburgh; and the delay, the means of saving which was thus shewn in regard to one day in the week, acquiesced in for all the other days.

One of the most remarkable steps which the post-office has made in advance, is usually and justly considered to be the adoption of Mr. Palmer's celebrated plan in 1784. The chief part of this plan, as is well known, was, to have the mails conveyed in charge of an armed guard, by the stage-coaches, (which thus became *mail* coaches) instead of by a boy on horseback, or mail cart, as formerly. The credit due to Mr. Palmer, is not perhaps so properly that of having discovered a means to an end, as that of having conceived and aimed at the end itself; for it is not easy to see how the increased speed and regularity, which were in effect obtained, were bound up in his specific proposal, or how (as the advantages of that proposal are sometimes described) the post-office was at once to borrow regularity from the stage-coaches, and the stage-coaches from the post office. Mr. Palmer's merit really consisted in seeing that a greater degree of speed and regularity in post conveyance was possible, which nobody saw but himself; and in catching the hint from the stage-coaches, which nobody else caught. The advantage of employing the stage-coaches instead of conveyances furnished expressly by the post-office, would seem to resolve mainly into the point of economy.

Mr. Palmer was afterwards appointed controller of the post-office, in which capacity he is understood to have made some important improvements in the internal details and arrangements.

The first mails on Mr. Palmer's plan, were the Bath and Bristol, on the 2d August 1784. Previously to the adoption of this plan, the ordinary speed of the post is said to have been but about three miles and-a-half in an hour. After that, the speed was doubled. At present, the average speed of the mail coaches, is eight miles seven furlongs, the highest reaching to ten miles five furlongs. This is exclusive of stops.

The number of miles travelled over in England and Scotland, by the mail coaches in 1833, was 5,911,006; in 1836 it was 6,643,217.[5]

Mails were first conveyed between Liverpool and Manchester, in 1828. Three communications took place daily between these towns, until September 1835; afterwards there were four, and latterly there have been six, from Liverpool to Manchester, and five the contrary way. The important line of railway connecting London with Birmingham, Liverpool, and Manchester, and extending northwards to Preston, having lately been opened, mails are now regularly transmitted by it from the capital to the various towns in the extensive and populous district through which it passes, and onwards to Scotland and Ireland, from its terminating points in each direction. A travelling post office is conveyed along the

History.

line, in which letters are sorted during the passage, the advantage of which will be afterwards explained. The only, or principal, other line of railway by which mails are at present conveyed, is that connecting Carlisle and Newcastle, but this mode of carriage must of course extend itself as new lines are completed. A late act[1] empowers the postmaster-general to require railway proprietors to carry the mails at a rate fixed by arbitration. The effect of the rapid transmission of correspondence by railway, increased as that rapidity yet may be, if there were added such a reduction of postage as has lately been proposed, would almost be that of bringing the inhabitants of the extremes of the kingdom into personal communication. The revolution which may thus be produced on trade, science, government, and social economy, it is hardly possible to calculate.

In the course of the last twelve or fifteen years, the facilities of communication, both inland and foreign, have been materially extended, by reduction of postage duties and otherwise.

Until the year 1827, letters passing between Britain and Ireland had been charged the added amount of the British and Irish land postage, severally taken. From that year, the rate has been calculated the same as if such letters had been conveyed the whole distance in Great Britain. At the same time, the law which required double postage to be charged on one sheet of paper with two letters written on it, or a letter and invoice, &c. was repealed, and a single sheet declared to be in any case but a single letter.[2]

In the year 1835 it was enacted,[3] that after an agreement shall have been made with the post-office of any foreign kingdom or state, it shall be optional with persons sending letters by post to such foreign kingdom, to pay both the British and foreign postage at the time of sending the same, or to send the same without payment of any part of the postage, or to pay the British postage only: persons residing in foreign kingdoms having the same option. Following out the powers given by this statute, a convention was entered into, and signed at Paris, on the 30th March 1836, between his Britannic Majesty and the King of the French, in which the requisite arrangements are made for giving the proposed option as to payment of postage on all correspondence between France, on the one hand, and Great Britain and Ireland, and those British colonies and possessions where the post-office of Great Britain has established post-offices, on the other. The postage between Paris and the British frontier is fixed at one franc, between London and the French frontier at tenpence, and in proportion for other distances in each kingdom. And though under the present arrangements the option of sending letters *without* payment is confined to those for France alone, letters may be sent through France, paid for the full distance, to any post town in Switzerland, Sardinia, Central Germany, or Bavaria; also to the Southern Italian States, as far as Sarzane, the Italian frontier of Sardinia, and to Austria, Bohemia, Venice, &c., as far as the French frontier offices of Huninguen or Forbach.

By the same statute,[4] the postage on letters sent by private ship from the United Kingdom to places beyond seas, (which until then had been *one-half* of the *packet* rates), was fixed at the uniform rate of eightpence, single, on letters posted at the port, and one shilling if posted at any other part of the kingdom. Letters were at the same time permitted to be sent abroad, from any port, by a private vessel, without passing through the post-office, or from one port to another, within the United Kingdom, by private ship, at a sea postage of eightpence.

In 1835, a post communication was opened up between Britain and India, through the Mediterranean, by which the course of post with that part of the world has been very greatly shortened. Letters for India can also be forwarded through France by steam boats sailing three times a month from Marseilles.

Very important facilities and immunities have recently been given in regard to the transmission of *newspapers*.

At first the transmission of newspapers seems to have been a privilege confined to certain officers in the post-office. In 1763 an act was passed,[5] giving the sanction of law to what then seems to have become the current practice, namely, that of allowing newspapers to be sent free by members of Parliament and certain public officers, when signed on the outside by their hand, or *to* such members at any place of which they had given notice in writing to the postmaster-general. By gradual relaxations, the restrictions on the free transmission of newspapers degenerated into a mere form, that of printing or writing a member's name on the cover; and in 1825 an act[6] was passed, rendering even the observance of this form unnecessary. The same act, as subsequently amended,[7] allowed printed newspapers to be sent to the colonies, by the packet boats, at a postage of one penny halfpenny each paper, and colonial newspapers to be brought to Britain and Ireland, by packet or private ship, at a postage of threepence. In 1834[8] the postage on newspapers sent to the colonies by packet, and on colonial newspapers brought by packet, was wholly taken off. At this time, too, a most important enactment was made in regard to the transmission of newspapers to and from foreign states. Hitherto the power of such transmission (unless at an expense amounting to a prohibition) had been enjoyed exclusively by certain officers in the post-office, from whom individuals could only obtain the accommodation at a considerable charge. By the statute now passed, British and Irish newspapers were allowed to be sent to foreign states, and foreign newspapers received into Britain and Ireland at a postage of twopence for each paper. A later statute[9] extends the accommodation still farther, by a clause authorising the postmaster-general to allow newspapers to pass free to and from such foreign states as grant a corresponding allowance in regard to Britain; or even, if he sees fit, without such a reciprocal arrangement on the part of other states; or to impose in any case an equivalent duty. And, by virtue of these provisions, there is now a free transmission of newspapers between Britain and the following states and places abroad: viz. Hamburg, Bremen, Cuxhaven, Denmark, Spain, Greece, Ionian Islands, Hayti, Buenos Ayres, Brazil, Columbia. British newspapers are sent to France without any charge in this country, but pay four centimes there. Newspapers *from* France are charged one halfpenny in Britain.

At this time also newspapers to or from penny post towns, passing through the general post, were freed from penny postage.

To these facilities for the circulation of newspapers is to be added that arising from the important alteration in the stamp laws, by which the duty on newspapers was reduced, from and after the 15th September 1836, from $3\frac{1}{3}$d. (nominally 4d.) to 1d.[10]

Business and establishments.

In proceeding to give a brief account of the post-office business and establishments, it may not be improper to advert to the new and improved accommodation lately provided for the use of this department, in the metropolis. About the year 1815 the premises in Lombard Street being found, after every possible enlargement, to be quite inadequate for the uses they were required to serve, measures were taken for the erection of a more ample, commodious, and elegant structure. It was not, however, until Septem-

Business and establishments.

ber 1829, that this purpose was finally accomplished, and the new building brought into a state of readiness for the public service. It is constructed of Portland stone, after a design by Mr. Smirke, and is in length about 390 feet, width 130, and height 64. The principal front, towards the west, in St. Martin's-le-grand, is composed of three Ionic porticos, that in the centre surmounted with a pediment. The middle space in the interior, lying between the principal and back entrances, is occupied by a hall of eighty by sixty feet in extent, having a range of columns and pilasters on each side. On the right, or south side of this hall, are the secretary's, accountant's, and receiver-general's chambers, together with the foreign letter and twopenny post-offices. The opposite side contains the inland, the newspaper, and the ship-letter offices. The mails, inwards and outwards, pass through a vestibule on the eastern front, communicating with the inland office. The latter is nearly ninety feet in length, and about fifty-six in width; the letter-carriers', or newspaper office, adjoining the inland, 103 by 35. The building contains a variety of other apartments for the different branches of the service, general and particular. To avoid the inconvenience and confusion of communication, through the public hall, between the departments on each side of it, the letters are conveyed from the one to the other through a tunnel below, by means of a curious machinery contrived on purpose.

The office at St. Martin's-le-grand, may be said to consist of two distinct establishments; one is the *general* post-office, properly so called, or that devoted to the post business of the empire in general; the other is just the post-office of *London*. In the first division, under the post-master-general, are the departments of the secretary, accountant, the dead letter, mail coach offices, &c. The principal departments of the second division, are the *inland* and *twopenny post* offices. The former has charge of the dispatch of the London letters and newspapers, and of those from abroad, passing through London, to all parts of the kingdom. It also manages the delivery of all those arriving at, and destined for London.[1] Subject to this department there are seventy receiving-houses within a circle of three miles from the office. Within this circle letters are taken in and delivered without any charge beyond the general post rates. The inland office employs eighty-four clerks, two hundred and ninety-one subsorters and letter-carriers, and about fifty messengers, stampers, &c. The most arduous business of this department, that requiring the greatest energy and rapidity, is the dispatch of the mails, in number twenty-nine, at eight o'clock each evening. So near has the time up to which letters and newspapers are received, been brought to the hour of dispatch, and such is the increase of business, particularly in regard to newspapers, that it almost exceeds the utmost efforts of the persons engaged to accomplish the duties within the limited space. By an account kept on the 19th February 1838, it was found that of 47,795 letters received at the inland office, up to fifteen minutes before eight, only 9,428 had arrived before half-past five, and 9,842 came in after seven. The sum of 6d. charged on each letter taken in during a limited time each day after the receiving box is shut, amounts to above L.1000 a-year. Sometimes 30,000 newspapers are received within the last fifteen minutes allowed for taking them in. The letters are successively stamped, sorted into divisions corresponding with the principal lines of road, taxed, (or marked with postage, after the necessary examination,)[2] and subdivided for post towns. The amount charged on each postmaster is then told, and entered in his bill, and duplicate preserved. From thirty-five to fifty-five persons are employed in sorting, twenty in taxing, and as many in telling up. The newspapers are sorted by the letter-carriers in their own office: from 120 to 300 being thus employed on different days. Six or more are occupied in examining newspapers, to detect private communications, enclosures, &c. From forty to sixty newspapers are charged daily, the postage amounting to L.100 a-week. After all these operations are finished, the bags are to be filled, tied, sealed, and delivered to the guards. The daily average of letters dispatched from London is 36,000. On Mondays the number is from 40,000 to 50,000. The number of newspapers dispatched from London in the last three months of 1835, was 3,146,127; of 1837, 5,020,230; the one period being previous, the other subsequent, to the reduction of the stamp duty. On Saturdays and Mondays, when the numbers are greatest, (sometimes exceeding 100,000,) it is necessary to engage one or two outside seats on the coaches for their conveyance. Sometimes they are sent separately by the stage-coaches. About 3000 are sent by the Edinburgh mail. The weight of the Edinburgh mail, as ascertained by one evening's trial, was as follows: sacks and bags, 1 cwt. 9 lb. 8 oz.; 2296 newspapers, 2 cwt. 2 qrs. 3 lb. 8 oz.; two stamp parcels, 1 qr. 12 lb.; 484 franks, 1 qr. 19 lb. 15 oz.; 1555 chargeable letters, 1 qr. 6 lb. 14 oz.; in all, 4 cwt. 2 qrs. 23 lb. 13 oz. The weight of the Holyhead mail on the 30th June 1838, was: bags, 1 cwt. 10 lbs.; letters, 1 cwt. 2 qrs. 17 lbs.; Newspapers, 15 cwt. 1 qr. 18 lbs.

In the morning, on the arrival of the mails, the bags are counted and inspected, to ascertain that all have arrived, and with the seals secure; after which they are emptied, and turned inside out, and the amount of the postage marked on the paid letters compared with the account sent by the postmaster. The letters then undergo an examination, in order to its being seen that all have been rightly charged, as single, double, &c. Being then stamped, they are distributed into several larger divisions, as those for the twopenny post, for the window-men, and for the different districts of the town; which last divisions are again subdivided for the walks of individual letter-carriers. Each of the different persons to be engaged in the delivery is then required to tell the amount of postage on that portion of the letters committed to him; and on his reporting an amount corresponding with that brought out by a separate telling previously made, but not communicated, the charge becomes established, and is signed by the party. In case of difference, reference is made to a third person. Each man's letters being then arranged, the delivery commences. The letter-carriers having the more distant walks, are conveyed to the ground by omnibuses, (of which ten are employed for this purpose,) each man being dropped at the commencement of his walk. In the morning duties, there are fifteen persons employed in opening the bags, and checking the accounts; nine in examining letters; fifty sorters; and ten tellers. The number of letters arriving in London daily, is from 30,000 to 40,000.

There is a separate department for dispatch and receipt of foreign mails, and another for the same duties in regard to ship-letter mails. Masters of vessels are allowed 2d. for each letter brought from, or carried abroad.

The number of letters from France in the year 1837, was from 30,000 to 36,000, and about half as many more in transit, through France. Letters expedited to France, from 33,000 to 39,000; in transit through France, from 11,000 to 15,000. Newspapers sent to the continent of Europe, about 30,000 per month; received, about 20,000.

The London penny, or twopenny post, was first set on foot by a person named Murray, an upholsterer, about the year 1683, and by him assigned to one Dockwra. A suit, however, was commenced against the latter by Government, and the management of this post withdrawn from him. But he received an indemnification, and was afterwards appointed controller of the office. The present limits of the twopenny and threepenny posts were fixed in 1831.

---

[1] Foreign mails arriving after the general post delivery, are delivered by the twopenny post letter-carriers.

[2] Stamping is performed at the rate of from 100 to 200 letters in a minute; examining and taxing, 33; and sorting, 30.

A *penny* or *twopenny* post-office delivers and collects the correspondence of a particular *portion* of the district belonging to any principal office. In the former respect, (however the duties may be farther subdivided,) it just performs the part of one letter-carrier, with merely the difference of the additional charge on the letters. All letters arriving by the general post at London, for parties residing beyond a circle of three, and within a circle of twelve miles, are transferred to the twopenny post department for delivery; and letters posted for dispatch within the same space, are collected by this department, and transferred to the general post. Such letters are charged 2d. in addition to the general post rates. So far the London twopenny post performs exactly the same functions as any of the penny posts in other parts of the kingdom. It differs from them in so far as it collects and delivers *all* the *local* correspondence, not merely in its own *portion* of the district annexed to the principal office, but in the whole of that district: having its own receiving houses, and its own letter-carriers, within, as well as beyond, the circle of general post delivery. Letters both posted and delivered within the three-mile circle, are charged with a postage of twopence; those crossing beyond it into the space within the wider circle, or *vice versa;* also those both posted and delivered between the inner and outer circles, threepence. The twopenny post subdivides its duties within the three-mile circle, among four branch offices, besides the chief office of the department. The correspondence to and from these, as well as to and from the district beyond the three-mile circle, is conveyed by horse posts, or mail carts. The rides to the country are ten in number, some dividing into two branches, besides four cross rides. There are 209 twopenny post receiving houses[1] within the three-mile circle, and 194 in the country, and 640 letter-carriers and assistants, of whom 270 are employed within the smaller circle. Seven collections and deliveries take place daily within the three-mile circle, and from two to six between it and the outer one. The whole of the twopenny and threepenny post letters, wheresoever collected, are carried to the chief office, and reissued from thence, with exception only of those passing between receiving houses lying in the line of one ride.

The whole number of persons employed on the London general and twopenny post establishment in 1835, was 1338. This includes the country surveyors, 7, and mail guards, 228. In the same year there were 258 persons on the Dublin, and 97 on the Edinburgh establishment.[2] But there has been some increase since.

The number of post-offices is constantly varying. At present they may be stated about as follows: England 649; Scotland 211; Ireland 328: Sub-offices[3] in the three kingdoms, respectively 191—105—102: Penny posts 1085—225—197. *Convention* or *fifth clause* posts in England 50. There are 42 offices in the interior of Jamaica, and 337 in British North America.

There are in England, Scotland, and Ireland, 194 mail coaches and other carriages; 217 saddle-horse posts; 374 mail carts, and 806 foot posts.

The following are the numbers of letters and newspapers posted at all the offices throughout the United Kingdom, in the week commencing 15th January 1838:

General post letters, paid,		164,719
... unpaid,		776,543
Penny post, ... paid,		16,998
... unpaid,		123,773
Privileged,		122,901
Total,		1,204,935
Of which		
For England,	916,815	
... Scotland,	128,584	
... Ireland,	159,536	
		1,204,935
Total newspapers,		842,646

London twopenny post, (not included above,) total letters, 231,900; newspapers, 10,724.

In the week commencing 29th January, the total number was (including the London twopenny post) 1,550,620,—the postage amounting to L.45,509: Newspapers 858,927. In the week commencing 5th March, the proportion of the classes of general post letters was, (in the united kingdom), single, 699,182; double, 38,562; treble, 11,358; ounce, 1,908; above an ounce, 2447.

The number of charged newspapers returned to the dead-letter office in London in 1837, was above 19,000. The number of undelivered letters, opened and returned to the writers, are about 20,000 in a month.

The total number of ship-letters (*i. e.* letters by *private* ship, not post-office packets,) both sent and received through all the posts in the kingdom was,

For the year ending 5th January 1834,	1,044,000
... 1838,	1,547,000

The two principal ship-letter ports are Liverpool and Hull; the former being the great channel (by the weekly packets) to America; the latter (by the steam-boats to Hamburgh twice a-week,) to Germany and the north of Europe. The number of letters sent by these, was,

	Liverpool.	Hull.
For the year ending 5th January 1834,	15,318	15,797
... 1838,	63,116	47,457

The regular mail packets for the conveyance of foreign and colonial correspondence are as follows:—

To France, every day except Sunday, by Dover and Calais, (steam). To Belgium, by Dover and Ostend, four times a-week, (steam). To Hamburgh from London, twice a-week, and to Holland by London and Rotterdam, twice a-week. (These two mails are conveyed by contract in private steam-vessels.)

From Falmouth, to Lisbon, Cadiz, and Gibraltar, once a-week, (steam). From Gibraltar to Malta, Greece, and Ionian Islands, once a-fortnight, and from Malta to Egypt and India, every four weeks, (steam).

To Jamaica, St. Domingo, and Leeward Islands, once a-fortnight, carrying letters to La Guayra one fortnight, to Carthagena the other. To Mexico and Cuba, monthly.

To Halifax, North America, monthly. To Madeira, Brazil, and Buenos Ayres, monthly.

The mails are conveyed between the West India islands by steam-boats, on contract.

On the Falmouth station, there are thirty vessels employed in the packet service, six at the Dover station, and eight steam vessels from the Thames.

---

[1] A consolidation of the general and twopenny post receiving-houses, within the three-mile circle, is understood to be now resolved upon.

[2] *Parliamentary Paper*, No. 442. About ninety years before this period, (the Earl of Leicester and Sir John Eyles being postmasters-general) the London *general* post establishment consisted of 157 persons. About the same time the Edinburgh establishment (Sir John Inglis being deputy postmaster-general) consisted of eleven persons, including three letter-carriers, and an officer designated "apprehender of private letter-carriers." *(Present State of Great Britain*, by Mr. Bolton, 1745.)

[3] Sub-offices differ from penny posts merely in having their letters charged according to *distance only*, as in principal offices. *Fifth clause* posts, (so called from the clause of the act 41st Geo. III., under which they are established,) are posts to villages, the inhabitants of which become bound for any deficiency in the expense of maintaining them.

Business and establishments.

For communication between Britain and Ireland, there are packets from Liverpool and Holyhead to Kingston, from Milford to Waterford, and from Port-Patrick to Donaghadee. There are also packets from Weymouth to Guernsey and Jersey, Liverpool to Isle of Man, Aberdeen to Shetland, &c.

Until about fifteen years ago, the post-office had the whole charge of procuring, fitting out, and maintaining the different mail packets. About that time the Falmouth packets were transferred to the Admiralty. A further transfer of most or all of the others was recommended by different commissions appointed to inquire into the management of the post-office, and carried into effect last year, (1837). The grounds of this recommendation were, that the duties required for the efficient and economical management of the packets, were such as the peculiar habits and qualifications of the heads of a civil department did not adequately fit them to perform. A great saving has accordingly been effected by the change of management. The packet communication with France is regulated by treaty made in 1833; and that with Belgium by a similar treaty made the following year.[1] France maintains her own packets for carriage of the French mails to Dover; but receives from L.10,000 to L.12,000 annually from Britain for transit postage of letters carried through her dominions to Italy, Turkey, Switzerland, Spain, &c., according to a scale fixed by the treaties of 1802 and 1836. Out of this, however, she has to pay to Austria the transit duty of letters passing through that country. Hamburgh and Holland pay nothing for having their correspondence conveyed by British packets, but charge no transit. Belgium also charges no transit against Britain, and moreover pays L.1000 yearly for packet conveyance, there being four weekly mails to that country, and only two to Hamburgh and Holland. From L.200 to L.300 a-year is paid by Rio Janeiro.

The mode in which letters are circulated, and the post revenues collected, is as follows:—Each of the three capitals, London, Edinburgh, and Dublin, sends a bag direct to, and receives one direct from, every office in its respective division of the kingdom. Every postmaster sends a bag to every office on the different lines of road leading from his own, as far as the first office (inclusive), at which the mail conveyance makes a stop. Into the bag for the most distant office, are put all the letters (tied up together indiscriminately) that are for places beyond it; and which, accordingly, are here sorted into the bags for each place, as far as that, inclusive, where the next stop takes place, and where the same process is repeated. Letters thus sent to another office to be sorted and forwarded are called *forward* letters. Such as are to go off at a cross line, are sent, as forward, to the office from which the cross line diverges. This is the general principle of the circulation. The moving post-office on the railway answers all the purpose that a sorting office interposed between every two stations on the line would do, at the same time saving the necessity of stoppage. Every office conveys its letters, as *forward*, into the moving one as it passes. In it, the mails for the station next occurring are immediately made up, ready against arrival there: the letters going to stations beyond being separated, so to speak, as forward on the *position* of the moving office, after passing that station. Letters are *taxed* (or marked with postage) as well as stamped, at the office where they are put in; and with every bag is sent a bill containing simply two *items*, namely, the amount of postage for letters in the bag, chargeable on the *sending* postmaster for *paid*, and on the *receiving*, for unpaid. The bill consequently does *not* include the *paid* postage on letters from offices *behind* the sending postmaster's, nor on *unpaid* letters going *beyond* the receiving postmaster's: the former having been already charged, the latter afterwards to be charged on other offices. Thus the postage on every letter whatever, paid or unpaid, is brought to the charge of one office or another. Both the items of every bill are entered in an account at each of the two offices to which its contents relate; the one account checking the other, and the bill remaining to settle differences if any; and when the accounts are summed, the charge against each postmaster is just his *sent paid*, and *received unpaid*. This charge he liquidates either by actual remittances, by allowances to his credit for his own salary and other payments, and by his dead-letter account. The last is vouched, first, by dead-letters actually returned; secondly, by receipts for overcharges; and thirdly, by claims for letters *re-sent* to other offices; which claims, as noted on a form prepared for that purpose and transmitted along with the re-sent letter, are certified by the receiving postmaster; and being forwarded to the inspector of dead-letters, serve to check the claimant's account.

Rates.

The country postmasters' remittances are made to the secretary, who transfers them over to the receiver-general, after furnishing a note of the amount to the accountant, who from thence credits the postmaster, and debits the receiver-general. The revenue collected at the general post-office is paid direct into the hands of the receiver-general by the persons actually collecting, who are merely the window clerks and the letter-carriers; the charge against each, certified by the parties as admitted, being furnished at once to the receiver-general and the accountant by the superintending officer. No account of the *paid* letters is sent from the general to the country offices; the check being there maintained between one department and another. Postmasters advancing the charge on a letter observed to be under-taxed, are required to put their initials to the alteration, which, if the letter is for their own delivery, is in effect sending out a receipt for the additional charge.

The deputy postmasters-general in the colonies are charged with the amount of letters sent them by each mail, in the same way as the country postmasters within the kingdom; the method of check and account between the internal colonial offices being also the same as between the different country offices at home.

Rates.

The present rates of inland postage in the United Kingdom are as follows:—

	Britain.	Ireland, (for same distance in *Irish* miles.)		
	d.	*d.*	*d.*	*d.*
For any distance not exceeding 8 miles,	2	0	2 and	3
Above 8, not exceeding 15 ...	4	0	0 ...	3
... 15, ... 20 ...	5	0	0 ...	4
... 20, ... 30 ...	6	0	4 and	5
... 30, ... 50 ...	7	5	6 and	7
... 50, ... 80 ...	8	7	8 and	9
... 80, ... 120 ...	9	0	9 and	10
... 120, ... 170 ...	10	0	11 and	12
... 170, ... 230 ...	11	0	12 and	13
... 230, ... 300 ...	12	0	13 and	14

And for every 100 miles above 300, (or fractional part of that distance,) one penny additional.

If the *amount* of all the rates in this scale is taken, and divided by the *number* of rates, it will yield an average of 9d. A similar process applied to the scale of 1710, gives 3½d. for the average. The increase in the intermediate period has been almost gradual, though the intervals between the alterations have been very different. There was no alteration from 1710 to 1765. Since that time, either in the British or Irish, there have been ten alterations. In 1800 the average was 5½d.; in 1810, 7½d.

The sea rates from Port-Patrick, Holyhead, or Milford

---

[1] *Sixth Report of Commissioners of Post-Office Inquiry.*

Haven, and Liverpool, to Ireland, are respectively 4d., 2d., and 8d.; from Weymouth to Guernsey and Jersey, 3d.; and from Liverpool to the Isle of Man, 6d.

The packet postage from *London* to France is 10d.; to Switzerland, 1s. 2d.; Holland and Belgium, and Germany, *via* France, 1s. 4d.; Germany and north of Europe, (by Hamburgh,) 1s. 8d.; Spain, Italy, and Turkey, *via* France, 1s. 7d.; Spain, *via* Cadiz, 2s. 2d.: to which is to be added the inland rate to London, *less 2d.*, from any office in the country, where a letter may be posted. From *Falmouth* to Portugal is 1s. 7d.; Madeira, Azores, and Canaries, 1s. 8d.; Brazils, 2s. 7d.; West Indies and North America, 1s. 3d.; and inland postage to Falmouth, *less 1d.*; to Buenos Ayres, Chili, Peru, 2s. 5d.; St. Domingo, 1s. 3d.; Carthagena, La Guayra, Mexico, Honduras, Cuba, 2s. 1d.; and the full inland postage to Falmouth. To Gibraltar, Malta, Ionian Islands, Greece, Egypt, and India, (by steam from Falmouth,) a uniform rate of 2s. 6d. from all parts of the kingdom. To Cape of Good Hope, East Indies, New South Wales, and Van Diemen's Land, 2d. more than the inland postage.

Letters *from* India, Van Diemen's Land, Cape of Good Hope, &c., 4d. *a letter* above the inland postage; from other parts of the world by private ship, 8d. a *single* letter, and in proportion for double, &c. The charge on ship-letters *outwards*, has been already noticed.

All letters to places abroad must be paid at posting, except packet letters for the British colonies in America and the West Indies, or for France. Failing of this, the letters are opened at the dead-letter office, and returned to the writers.

Letters to and from soldiers and seamen in the service, pass through the whole British dominions for a postage of one penny, payable in advance.[1]

Letters under an ounce weight are charged single, double, or triple, according to the number of pieces of which they consist; triple being the highest rate below that weight. An ounce is charged four single postages, and every additional quarter of an ounce, a single postage more.

Exemptions.

Certain public officers, nearly a hundred in number, have the privilege of franking without any limitation either as to weight or number of letters. Every member of parliament can send ten and receive fifteen letters a-day, free; each letter not exceeding one ounce in weight, and being to and from a place within the United Kingdom. On occasion of passing the bill for the regulation of the post-office in 1657, "a proviso was tendered for freeing members of parliament and other officers of state from payment of any money for letters, which was laid aside without a question."[2] Freedom from postage, however, was claimed by the House of Commons in 1660, but the claim was afterwards dropped on an assurance from the crown that the privilege would be allowed. Accordingly, a warrant was always issued to the postmaster-general directing the allowance to the extent of two ounces in weight.[3] The privilege, however, was abused to an enormous extent, so much so that the servants of members sometimes procured a number of franks for the purpose of selling them. Occasionally, too, considerable frauds were practised by writing promissory notes or other instruments over the signature of a member given on a blank cover. Many curious devices were used by members in writing their signature to prevent this.[4] The estimated postage of franked letters in 1715 was L.23,600; in 1763 it had risen to L.170,700. Until that period, a letter passed free simply by the signature of a member. Even the requirement made by the act passed in 1763,[5] that the whole superscription should be in the member's hand-writing, was found an insufficient check to the abuse; and it was further required by the statute of 1784,[6] that the direction should bear the name of the post-town, and the day, (written in words at length) month, and year of posting. Letters can be franked from any post-town which the member has been within twenty miles of, on the day of, or day before date. They cannot be delivered but for full postage at a place where the member himself is not, (as to any agent or relation,) unless at his residence in London, or his proper house of parliament. Printed votes and proceedings in parliament pass free under certain regulations to and from members of parliament and some public officers. Petitions to parliament, not exceeding six ounces in weight, may be sent free to any member in covers open at the ends.

Revenue.

In 1653, the post-office revenue was farmed for L.10,000; in 1663 it yielded L.21,500; in 1685, when made over to James II. as part of his private income, it was estimated at L.65,000. The average of the nett revenue, during the eight years of King William's wars, is stated[7] at L.67,222; during four years of subsequent peace, at L.82,319; the average of the years 1707—10, at L.58,052; of 1711—14, at L.90,223. The gross in 1711,[8] was L.111,426. In 1722 the gross was L.201,804, nett L.98,010. From that period till after the middle of the century, the revenue, though of course, subject to occasional fluctuations, made on the whole but little advance, since we find that of the year 1754 to be only, gross, L.210,663, nett, L.97,365. Its progress for the remainder of the century, taken at intervals of ten years, (each ending 5th April), may be seen as follows:[9]

	Gross.	Nett.	Rate per cent. of Collection.
1764,	L.242,566	116,128	52
1774,	334,829	164,077	51
1784,	452,404	196,514	56
1794,	915,608	431,981	40
1800,	1,083,950	720,981	30

From the beginning of the present century the revenue continued increasing progressively until the year ending the 5th January 1816; the following year it was considerably lower, and never rose to such an amount again, until the corresponding year 1837, when it reached its highest. The following table exhibits the particulars; (the Marlborough grants, &c. are not included in the charges of collection.)

---

[1] There are other descriptions of special, and modifications of general rates, which would require too much space to particularize. The system of rates is full of the most preposterous niceties and anomalies. It is but fair to state, however, that some attempts have lately been made to introduce greater uniformity, as in the ship-letter and Mediterranean rates.

[5] 4 Geo. III. c. 24.

[6] 24 Geo. III. c. 37.

[7] Chambers's *Historical View of the Domestic Economy of Britain*. The *gross*, on a medium of three years prior to 1698, is stated by D'Avenant at L.90,440.

[8] The revenue, as stated for the years previous to 1711, are believed to include the *Irish*. From that year to the end of the century, the account given relates to the *British* revenue solely; the Irish, for this period, not being stated in any of the documents from which the account is taken. In comparing different accounts of the post-office revenue, even including those found in parliamentary documents, the most puzzling discrepancies are to be met with. These, however, are not so much, if at all, to be ascribed to error, as to differences, not expressed in the subjects of the statements. Sometimes the Irish, or twopenny post revenue is included, sometimes not; the revenue for a year, ending 5th April or 5th January, is sometimes given as the revenue for that, sometimes for the preceding year; the *nett* sometimes means the remainder after deducting from the gross the simple charges of management, sometimes after farther deduction of returns, parliamentary grants, &c.

[9] *Second Report of Postage Com. Ap.* p. 176. The nett is after deduction of returns. In 1782, the expense of collection was 72 per cent.

Smallest ditto................	„ 1822	stated	above.					

The *gross Irish general* post revenue for the *year ending 5th January* 1800, was L.84,040; it increased progressing until 1816 when it reached L.225,000; it never attained so high again until 1829, from which it continued increasing till 1832, when it reached its highest, viz. L.256,976. In 1837 it was L.255,070. The lowest amount after 1816 was that of 1823, which was L.186,024. The highest *nett* in the whole period was in 1832, viz. L.154,322; the smallest after 1816, was 1821, viz. L.65,017. The highest rate per cent. of collection, January 1800, L.70, 9s. 2d., lowest, 1832, L.32, 11s. 9d.

The gross receipts of the London twopenny post in the year ending January 5, 1804, was L.60,069; 1837, L.120,801; *nett* for the same years, L.35,640 and L.73,334; rate per cent. of collection for the same years, L.40, 13s. $3\frac{3}{4}$d. and L.39, 5s. $10\frac{1}{4}$d.

It is related[2] that in the year 1698, Sir Robert Sinclair of Stevenson had a grant from King William of the whole revenue of the post-office of Scotland, together with a pension of L.300 to maintain the post. Even with this allowance, however, the undertaking was considered hazardous and the grant surrendered. At the union, the post-office revenue was farmed for L.1194. The nett revenue, on an average for three years preceding 1711, was estimated at only L.2000; in 1733 it was L.5399; in 1754, L.8927; in 1776, L.31,103. In the year ending 5th January 1801, the revenue was, gross, L.100,652, nett, L.83,755. It increased progressively till the corresponding year 1815, when the gross was L.203,366, nett, L.161,551. In 1822 the gross had sunk to L.179,404, whence again it took a start in the other direction, and in 1837 was L.220,759, nett, L.160,813. The expense of collection in the present century has varied from 14 to 28 per cent.[3]

The amount of postage charged on postmasters in the West Indies and British North America in the year ended 5th January 1838, was L.78,905, of which above L.18,000 was for unpaid letters from Britain. Of the first sum, there was for Canada, L.38,977, for Jamaica, L.18,274.

Laws.

The postmaster-general is not responsible, under any circumstances, for the safety of letters passing through the post-office, nor for the value they may inclose, if lost or stolen. This point was first settled in the case, Lane *v.* the Postmaster-General, in 1699, (reported in Raymond, vol. i. p. 646). Some doubts hanging over the principle of this decision, the point was again tried, before Lord Mansfield, in 1778, (Whitfield *v.* the Postmaster-General, Cowper's Reports, p. 754,) and judgment given for the defenders. The punishment of death for letter stealing was abolished in 1835,[4] and transportation substituted. Forging, or altering a frank is punishable with seven years' transportation. A newspaper with an enclosure, or any writing or marks, is subject to three times the postage of a packet of equal contents: which postage may be recovered from the sender,[5] or the postmaster-general may prosecute as for a misdemeanour. Masters, crews, or passengers of vessels from abroad, failing to deliver their letters at the first post-office, incur heavy fines. Penalties and postage debts not above L.20, are summarily recoverable. Letters once posted become the property of the person addressed, and cannot be again withdrawn. Other laws (those against illicit conveyance being frequently made public) are of less general concernment.

In the year ending October 1834, there were fifteen criminal prosecutions in England for post-office offences, and twelve convictions, some of them capital; and thirty-four prosecutions for penalties, in which the parties submitted.

The whole acts relating to the post-office have been consolidated into five statutes, viz. 1 Victoria, ch. 32—36.

Alleged defects, &c.

The British post-office has generally been allowed to be remarkable for the precision and regularity with which it circulates the correspondence passing through it, and the celerity with which the official business is conducted; and the prevalent opinion has until lately been, that the department, on the whole, has been skilfully and efficiently administered. Instances, however, both of defects and mismanagement, have, within these few years, been somewhat frequently brought forward, and perhaps with a degree of exaggeration answerable to the indifference with which they had in former periods been regarded. As respects, in the first place, the *constitution* of the department, the inexpediency has been maintained of having the supreme direction vested in a single person, generally a nobleman, removeable at every change of government, and who, by his education and habits, cannot be supposed peculiarly fitted to superintend an establishment, possessing fully more of a commercial than of a civil, or even fiscal character. The tendency, and even the actual effect of such a system has been alleged

[5] The postage of all returned letters is recoverable from the *sender*, (1 Vict. c. 34, § 2,) but the law has not hitherto been enforced.

Alleged defects, &c.

to be, that of removing the charge from the really responsible head, and throwing it upon a secondary officer. The abolition of the office of postmaster-general, and the substitution of a permanent board of three or more persons, has accordingly been recommended by successive commissions of inquiry; and a bill for giving effect to such recommendation has been twice sent up from the lower, to the upper house of parliament, but refused a second reading by the latter. As regards the *laws* of the post-office, the grand subject of complaint, and that on which perhaps the mind of the community is more made up than on any other, is the high rate of postage, both generally, and in particular cases, as for shorter distances, circuitous routes,[1] penny postage on general post letters, and the like. That there is a great fault in this respect, is argued from the fact of there being little or no increase on the annual revenue, for more than twenty years; and though this fact, to a certain extent, at least, admits of other explanations, it is undeniable that a large amount of correspondence is conveyed otherwise than by post, merely to avoid the expense of postage; and that the existing laws are insufficient, as would any laws be that could possibly be framed, to check such practice. The complaints against the *administration* of the post-office relate principally to the alleged want of sufficiently frequent and numerous communications on various lines of road, and the consequent delay of correspondence, of which the most important case is the want of day mails and Sunday mails[2] from London, there being at present but one day mail, and that but lately established. Without entering into a consideration of the justice of any of the complaints now enumerated, (the fact of their existence being all that it concerns the present purpose to notice), it may be remarked with regard to the *nature* of the particular class just adverted to, that they frequently resolve into questions between the interests of one portion of the community and those of another; or into similar questions between a portion and the whole; or between an advantage with a corresponding sacrifice, and the loss of such advantage; questions to which the administrators of the post-office, at least, profess and appear to have given full consideration, and, either in regard to what is done or what is contemplated, to have determined with a view to the best.

One cause of complaint of not unfrequent occurrence, namely, that regarding the losses that occur in the post-office, by the abstraction of letters containing value, may be said to have been of late in a great measure obviated by the establishment of a system of *money orders*, to be granted by one office, payable at another, to the amount of L.5, at an expense of from 6d. to 1s. 6d. Larger sums can, in general, be safely transmitted through banks.

Within these few years, a plan of singular boldness and ingenuity, and developed with the utmost perspicuity and fairness of intention, has been put forth by Mr. Rowland Hill; a plan which aims at the removal of several of the defects of the present post system, but the practicability of which is matter of much doubt and dispute. The main feature of this plan, as every body knows, consists in a proposal to reduce the postage of all letters under half an ounce weight, to a penny, to be collected by a stamp-duty on the paper of the letter or envelope. The great benefits of such a system as this are obvious, the objections are not less so. These (omitting minor articles) resolve chiefly into this dilemma; either the number of letters would not be sufficiently great to produce the required *gross* amount, or, if it were, they would be unmanageable without an additional expense that would as much diminish the *nett.* On Mr. Hill's part, the necessity of the alternative is denied. As respects the first branch of it, he calculates on as many letters as would be sufficient at once to keep up the revenue, and defray any additional expense, first, from the falling in of all the illicit and most of the franked correspondence; next, from the great number of letters that would be sent by persons who now cannot often, or at all, afford postage, and are restrained by fear or conscience from smuggling; and lastly from the variety of printed bills, lists, advertisements, &c., which may be legally sent otherwise than by post, but for which the post would be preferred at a low expense. On the other branch of the alternative he maintains, that, as regards the matters of receipt, despatch, and delivery, the post-office, by being freed from examining, taxing, and the *whole business of accounts*, would be relieved from a great part of the additional labour that would be imposed upon it by the increased number of letters; and, as to conveyance, that the estimated increase of chargeable letters, would add but by a very small proportion to the *weight* or *bulk* of the mails; the far greater part of which is made up of newspapers, parliamentary documents, and franks.[3]

French post-office.

The French post-office, after the modern system, had its

---

[1] Since this was written, it has been announced that postage is in future to be charged only for the distance by the nearest carriage road without regard to the actual distance the letter may be conveyed.

[2] It is, perhaps, superfluous to observe, that the subject of Sunday mails and deliveries, involves considerations of a nature quite distinct from those on which questions, relating to post accommodation usually fall to be determined.

[3] That a system promising so great a reduction in the expense of correspondence, would meet with extensive favour and support, is what might be expected; and, consequently, in estimating the weight of the testimony in its behalf, which such support is calculated to yield, it is necessary to distinguish between a desire for its adoption, and a conviction of its practicability; so that we may not ascribe to the latter, what may be wholly due to the former. It is to be remembered, too, that what is called the *practicability* of the scheme, is a very vague expression. In the strictest sense, it must mean practicability, consistently with the maintenance of the present revenue from the post-office, or a revenue not materially smaller; in another sense, the practicability of the plan may mean that its adoption would occasion no deficiency, but what could, and ought to be, otherwise provided for. The supporters of the plan differ in the *sort* of practicability which they ascribe to it; but a conviction of its practicability generally, has been expressed by so many individuals and bodies of men, qualified by their knowledge and habits to judge of such a matter, and so little likely to think with indifference of an embarrassment of the public finances, that a strong presumption of the intrinsic merits of Mr. Hill's plan is unavoidable. The subject has been taken up in most of the principal cities of the empire, by constituted bodies, or associations formed for the specific purpose. Regular inquiries have been instituted by the circulation of minute queries, and otherwise, with the view of ascertaining how far the present system is sufficient as a means of accommodation; how far, as a source of revenue, the duties it imposes are liable to be evaded; and what increase of correspondence by post, or decrease of illicit conveyance, might be expected to take place, under such a reduction of postage as Mr. Hill proposes. Numerous petitions from the most influential and respectable quarters have been presented to parliament, in behalf of Mr. Hill's plan. A Committee of the House of Commons, appointed on the 23d of November 1837, to consider, generally, the subject of a reduction of postage, and especially the merits of Mr. Hill's proposal, has, in the course of two sessions, during which it has been sitting, examined a great number of witnesses, officers of the post-office, merchants, literary men, agents of trading companies, and philanthropic associations, clergymen, and others; all descriptions of persons, in short, the most likely to be able to shew the working of the present system, and to estimate the probable effects of the new. The Committee has, at the same time, collected a vast body of statistical evidence relating to the post establishment, in regard to every particular bearing on the subject of the investigation. The results of the inquiry have been communicated in two voluminous reports.

That the present high rates of postage have operated, in one way, to the repression of correspondence altogether, and in another, to the diversion, into illegal channels, of a vast portion of its existing amount,—a portion much more vast than had ever previously been suspected; that in the latter way, they beget a disregard to the law, and produce that deterioration of the moral feelings, which actions requiring concealment, tend to generate; that, in both ways, they embarrass the motions of trade, check the dissemination of knowledge, curb the

French post-office.

origin early in the 17th century. As in Britain, its revenues at first accrued to the postmaster, and were next for a time farmed. In 1791, the French post-office yielded a revenue of 11,000,000 of francs; about thirty years later, the revenue had become nearly double, and in 1836 it amounted to 37,405,516 francs; the number of letters for that year being 78,970,561. The French post establishment is under the direction of a council, consisting of a chief, and two or more members. The French differs from the British office, in charging postage by *weight*, a mode usual throughout the continent. The French office has been remarkable for the facilities it affords to the circulation of printed matter. All sorts of circulars, lists, advertisements, and the like, may first be stamped on payment of five centimes, and then transmitted by post for ten centimes more, in whole about 1½d. British money. The number of such circulars passing through the French post-office is immense. The business of the Parisian office even exceeds that of the London, there being from forty to fifty thousand letters, and 100,000 printed papers of different descriptions, dispatched from the former daily, Sundays not excepted. The French post towns amount in number to about 1460, but the post accommodation is carried to the utmost possible extent, letters being delivered not merely within the towns and villages, but throughout the country generally.[1] The same degree of dispatch in post business has not, however, been attained in France.

United States post-office.

The post-office of the United States is under the charge of the general government. For a long period it was a source of expense, and it is only during the last six or seven years that it has yielded a revenue, which, however, is now rapidly increasing. The following particulars regarding its present state, are from a report of the Postmaster-General of the United States to the President. On the first of July 1837, the post routes were about 141,242 miles in extent, and the annual transportation of the mails upon them was: on horses and in sulkeys 11,999,282 miles; in stages and coaches 18,804,800; and in steam-boats and

[1] The average of each letter is about fivepence. In Britain, it is probably double this, at least. The charges of collection in France are about 50 per cent., in Britain 28 per cent.

---

exercise of the social affections, and confine the efforts of philanthropy; that the post-office, in short, is neither fully and effectually available for the purposes which it is the essential object of such an institution to serve, nor able to preserve the monopoly conferred upon it by law, from systematic and extensive violation; these are points which may fairly be considered as settled by the evidence given before the Committee.

The questions involved in the investigation, as far as it relates to the practicability of Mr. Hill's plan, have been partly of fact, partly of calculation, partly of conjecture and estimate. It being incumbent on Mr. Hill's part to make it appear that the increase of the number of letters would counterbalance the decrease on the postage of each, it became necessary to ascertain what is the actual number by which the present annual revenue is created, and annual expense incurred. This is a question of fact; how many letters at any definite reduced rate would produce the same gross revenue, is one of mere calculation; what increased number of letters might be consequent on such reduction, is one of conjecture. Even the first two descriptions of questions, however, have not been so easily determined as their nature would seem to promise. Actual returns beyond the suspicion of incompleteness or incorrectness are, under the circumstances of haste and perplexity, in which such returns can only be made, and the incapacity of some of those who have to make them, hardly to be expected; whilst, from the fluctuations in the amount of correspondence at different periods, a fair season for presenting an average is not easily fixed upon.* Even, however, after an agreement, actual or assumed, has been attained on this point, several of those differences on subjects of calculation (which, viewed in the abstract, might be supposed of impossible occurrence, but in point of fact, are so often found to occur in regard to the admissibility of *data* and the mode of applying them,) have arisen to complicate and embarrass the inquiry.

One cannot help observing that some of the calculations, the correctness of which has been made matter of dispute, refer to rather irrelevant points. Such, for instance, is that regarding the exact cost of the *conveyance* of letters, &c. in Britain. Mr. Hill's calculations on this point, are probably subservient to the single purpose of evincing the justice of a *uniform charge*, which is done by shewing that the cost of mere conveyance, as distinguished from other parts of the charge of postage, is so small, as to make mere distance an immaterial element in the adjustment of the rate. Without examining (and certainly without admitting) the correctness of Mr. Hill's statements on this subject,† it may be held as allowed, on all hands, that whatever considerations may exist, to justify, or even recommend, the regulation of postage according to distance, these considerations may fairly be made to yield to the advantage of *uniformity*, especially at a very low absolute rate. But conveyance being but a *part* of the expense of distributing correspondence,‡ the calculation now alluded to, goes to no farther end.

Equally irrelevant to the main question (except as facilitating a calculation of the increase of expense under the proposed system, if indeed they serve even for that) are all those *analyses* which Mr. Hill makes of the composition of the present post-office expenditure. It is obvious that, throughout the inquiry (so far as it relates merely to a point of *finance*, its sole relation as presently considered) the *nett* revenue now derived from the post-office, must be taken as a *standard*, by which, according as the revenue to be raised by Mr. Hill's system reaches or approximates to it, the merits of that system are to be tested. Consequently, in comparing Mr. Hill's plan with the present, we must take the expenditure of the post-office *as it is*, unless so far as a saving can be shewn to arise *specifically out of Mr. Hill's plan.* If any deduction, *otherwise*, is made from the charges of management, as applied to Mr. Hill's plan, the same deduction must be made from the present expenditure, thereby raising the *present nett*—that is, raising the standard that Mr. Hill is bound to reach, just in the same proportion that it raises his means of reaching it.§

The real question as to the increase of letters that would be necessary on Mr. Hill's plan, lies in the smallest possible compass. The *gross* revenue to be raised in a given year, after deducting L.71,755, arising from extraneous sources, supposed available under Mr. Hill's plan as well as the present, is L.2,390,515, or 573,723,600 pence. This revenue is at present raised‖ (taking Mr. Hill's own calculation) from fifty-seven millions of *general* post letters, eight millions of penny post letters, and thirteen millions of *twopenny* and *threepenny* post letters. On the *penny* letters, Mr. Hill calculates on no increase; the *twopenny* and *threepenny*, if reduced to a penny, he expects to increase threefold, making these three descriptions of letters amount to forty-seven millions. Forty-seven millions of pence, deducted from the 573,723,600, leave 526,723,600 to be raised from the *general* post letters, which Mr. Hill estimates (taking in the weights above the penny rate) to produce 1¼d. each. It requires 421,378,880 letters at 1½d. to produce this; and to give such a number, the fifty-seven millions (the present number) require to be multiplied by about 7½, that is, to be increased 7½ fold. Now this would only leave the present nett revenue, supposing the *expenses* to remain as at present. But Mr. Hill allows that a *sevenfold* increase of the number of letters would, or might, increase the expense of *internal* distribution by nearly half a million of pounds, (the difference between L.575,384,

* See Sir Edward Lees's evidence, Q. 9413.

† If postage is to be charged according to the actual cost of conveyance, as compared with the returns, then a letter for ten miles will often cost more than one for 100; if on an average of such cost as applied to the whole, then, of course, the postage will be uniform; but if the charge is to be fixed on the general principle, that the cost of establishing and maintaining a conveyance for a large distance, must exceed that for a small; and that conveyance for a large distance is worth a greater price to the *payer*, inasmuch, as generally it would increase the difficulty to him of getting his letter conveyed, (which seems the *actual* principle of the charge) then distance must be reckoned a fair element.

‡ In this particular, and otherwise, Mr. Hill's statements have been applied (though apparently not intended by him to serve such) to purposes of utter delusion and misrepresentation.

§ These considerations are not brought forward *as if in opposition to Mr. Hill*, (by whom, in his latter statement presented to the Committee, they are given full effect to, though apparently overlooked in his pamphlet) but in order that persons who desire to see the matter with their own eyes, may not be deterred by the apprehension of having to encounter a tedious or intricate calculation.

‖ This assumption appears incorrect, as supposing the year's revenue to be *wholly* raised from letters *posted in the United Kingdom*, without taking into account the postage of those *arriving* from abroad. And as, on the assumption in question, Mr. Hill multiplies the letters of one week by 53, instead of 52, (the postage of the week being but 1-53d of the year's revenue) a deduction of about a million of letters would fall to be made from his estimate.

United States post-office.

railroad cars 1,793,024. The number of post-offices on the 1st December 1837, was 12,089. The revenue of the department for the preceding year was D.4,137,056 . 59

The expenditure,..................................3,380,847 . 75

Excess of revenue..............................D.756,208 . 84

The average number of dead letters annually, is about 900,000. The number of letters delivered in the year, is estimated at 29,360,992. Free and dead letters about three millions more. The number of newspapers, pamphlets, &c. paying postage, is estimated at about 25 millions. Dead and free newspapers, four millions more.

The Americans charge in the same mode as the British, namely, by the pieces of which the letter consists. The rates are as follows : for a distance not exceeding

---

the present, and 1,035,833 the *prospective* expense.) To balance this, he has the estimated additional rate on foreign and ship letters L.200,000,* (supposing a way shewn of raising this) thus leaving, after an increase of 7½-fold, a *deficit* of L.300,000.

Let the fairness of this calculation be tested, and then let it be reviewed in comparison with that by which Mr. Hill brings out a quite different result, that is to say, nearly *as favourable* a result from an increase of five-fold as has now been done from 7½.

After having on grounds, the correctness of which have been in part already questioned, (and, for the rest, are neither admitted nor denied), raised the number of letters for a year, from seventy-four to seventy-eight millions ; he next, on a ground which, on a moment's reflection he would probably give up as untenable,† raises them to eighty millions. These, at 1¼d. each, would produce L.416,666. Increased five-fold, they yield L.2,083,330, The cost on inland distribution he makes L.868,967, which, together with L.112,162, (other branches of expenditure) makes L.981,129. This deducted from the gross, leaves L.1,102,201 for the nett ; to which he adds the two items just mentioned of L.196,000 and L.48,000, thus making the total nett L.1,346,201, or only something more than L.300,000 of a deficit on a *five*-fold increase. Now all that is necessary for the purpose of explaining how this more favourable result is brought out, is to compare the produce of his *five*-fold, with that of his *one*-fold. The former will be found just five times the amount of the latter ; and as the *one*-fold includes all descriptions of letters, penny, twopenny, and threepenny, five times the produce of the one-fold, of course, suppose an equal increase on all.‡

Finding the average postage of a letter is merely another method of arriving at the same result. The average postage of a *general* post letter, appears from the returns to be above 10d. An eight-fold increase (at 1¼d. on average for each letter) would therefore produce the same amount on the present number at 10d. Other two-folds of an increase would produce L.475,000, to which the L.200,000 for foreign and ship letters being added, there would be L.675,000 for additional expenses. While it is admitted then to be a *vague* statement, (vague as respects the estimate of the increased expense, which can only be a guess), it is believed to be a *moderate* one, to say, that on ten-fold increase of general post letters, with a three-fold increase on the *twopenny* and *threepenny* post letters, would be necessary to uphold the present revenue.§

This, indeed, is a calculation, both the *data* and the conclusions of which, any plain man who pays twenty shillings to the post-office in a twelvemonth, may verify on five minutes' reflection. Let such a one consider, whether the average of his *general* post letters can be less than 10d., and then say, if the average cost were reduced to 1¼d., whether it could require less than ten letters for one, taking into consideration the increase of expense, to uphold the present revenue?

Passing now from matters of calculation, to those of conjecture and estimate, we encounter, as may be supposed, a much wider diversity of opinions. This head embraces that most essential question,—what precise increase of correspondence might be expected under such a reduction as recommended by Mr. Hill. That an increase would take place which, absolutely speaking, may be characterized as immense, may be held as at all hands acknowledged ; but in specifying the probable rate of such increase, in relation to that which would be necessary for the safety of the revenue, there is every possible variety of estimate,‖ ranging from, "very considerable" up to "beyond calculation," from four to a hundred fold ; of which extremes the *medium* may be given as "ten-fold," or "increase that would keep up the revenue." It is obvious, however, that evidence of this nature requires to be received with some degree of deduction. Besides being mostly *conjectural*, it may be said to be all *ex-parte*, brought forward *in support* of the scheme, the eligibility of which was the subject of investigation. There is no opposing party. Government is constrained, in such an inquiry, to be neutral. To the administrators of the post-office, interference would be an invidious office, seeing that even their evidence is apt to be viewed as that of interested, or at all events, prejudiced persons. The cross-examinations instituted by some of the members of the Committee, would be required even as a counterpoise to the effect of leading questions put (certainly without the slightest appearance of unfair intentions) by the others. When to this is added the significant fact, that few, indeed, of the witnesses ventured to state, that they would pay as much postage under the proposed reduction as at present, (while an increase of outlay is admitted to be inevitable on such reduction) and that the generality only hoped for a surplus revenue equal to the present, after the lapse of a considerable period ; when we advert to another important fact, that scarcely one of the witnesses professed to have examined Mr. Hill's calculations, but merely to have *assumed* their correctness ; when these considerations are taken into account, it is surely not too much to say, that the adoption of the plan in question would place the post-office revenue in very imminent hazard.

But although Mr. Hill's plan has been perilled by some of his supporters, if not by himself, on this issue, that it would, at least, maintain the present revenue, its proved insufficiency *on this issue*, is not, on a larger view of the question, to be viewed as conclusive against it. Even in a financial point of view, a defalcation in this source of revenue would probably be met by a proportionate growth in others. The increased facilities given to trade, would, in a variety of ways, tend to the creation of revenue. Even the increase on the paper duties might not be an inconsiderable item, though perhaps liable to be balanced by a corresponding decrease on those on advertisements. Viewing the advantage to commerce, literature, and morality, which would arise from a cheap system of postage, there are probably few persons conversant with subjects of social or political economy, who would advocate the employment of the post-office as a source of revenue, on any other grounds than, in the present circumstances of this country, the difficulty of finding another as a substitute.¶

Put off the supposition, however, that such an increase of correspondence would ensue, as that which has been mentioned as the average

---

* Mr. Hill also claims, as a receipt to fall into him, L.48,000 for "payments by government offices not entitled to frank." But, it is presumed, the letters for which these payments were made on the year taken, were part of the 78,000,000 ; and, if so, query, farther, whether these ought not to be deducted from the number of increasable letters? The government officers would send no more letters at a penny than they do at present. In the uncertainty, however, as to the grounds of this claim, let it be allowed ; still the deficiency, after so great an increase, will remain a quarter of a million.

† The ground is, the high postage of ship and foreign letters which *came in* the week of the *return*, Q. 11032. But letters *arriving from abroad*, formed no part of the return, nor could their postage affect the question. It is but fair to say, however, that the suggestion on this point did not come originally from Mr. Hill.

‡ Is not this multiplying the penny letters in the same *ratio* with the others, as objected to by Lord Litchfield? It is true, that with the explanation that Mr. Hill would give it, namely, that by a *fivefold* increase, *he means* the average of a sixfold on the general post, and a threefold on the twopenny and threepenny, (the penny remaining the same) ; this would be merely a different mode of expressing the same thing. Practically, it is a deception ; because, any *increase* promised by Mr. Hill, being an increase *by virtue of reduced postage*, whenever he says that a fivefold increase would produce such and such a revenue, every body will understand him to mean, a fivefold increase of *reducible letters*, that is, (mainly) of *general post* letters. If Mr. Hill owns, as he would own that his statement, *in this meaning*, would be untrue, how can he complain of Lord Litchfield for supposing what would be necessary to make it true; namely, a fivefold multiplication of the *penny* letters, as well as of the others? In *substance*, then, there is an agreement as to the principle of the calculation; a difference as to the *data*—the number of letters from which a given revenue is *at present* drawn.

§ The average postage of a letter has been represented to be 6½d ; consequently, it is meant to be inferred, a sixfold increase, or little more, would produce the present revenue. But if this is the average *at all*, is it the average otherwise than by including the penny and twopenny letters? or would *these* increase sixfold? Do not the more unscrupulous supporters of Mr. Hill's plan, who blazon abroad partial statements of the kind, see that they prove too much? If 6½d. is the average of *increasable*, that is, of general post letters, (the sense intended to be conveyed) what becomes of the outcry about the exorbitant rate of postage? Tell a man, that for 6½d., at an average, he may have a letter conveyed, with the utmost possible speed, and with all but infallible certainty, to any part of the known world, and will he sympathise in the complaint of excessive charge? Mr. Hill's plan may safely be allowed to rest on its merits; let it be allowed to rest there, without the employment of deception and misrepresentation.

‖ The importance of keeping these two points distinct in the mind, is shewn from this, that Lord Ashburton is made, in the Appendix to the Report, to give evidence of the probability of a "great increase," while his Lordship explicitly states his belief, that the adoption of Mr. Hill's plan would be equivalent to a surrender of the whole post-office revenue.

¶ Might such a mode as this be suggested :—Let a bill be brought into Parliament, to grant her Majesty a certain revenue from *postage*, to be raised after the manner described by Mr. Hill ; but containing provisions, that any deficiency of such revenue is to be supplied from other *defined* sources. Let these sources be named by the Chancellor of the Exchequer, or offered by the supporters of Mr. Hill's scheme, (to which the latter could not object, as on their principles the provisions would be inoperative for want of occasion ;) but, at all events, agreed upon as an essential part of the bill.

Postulate

Potatoes.

Ship letters at the port of arrival, 6 cents; 2 cents more than the inland postage, if carried inland. Newspapers 1 cent, or 1½. Magazines and pamphlets from 1½ cent to 6 cents per sheet, according to mode of publication and distance.[1]

POSTULATE, in mathematics, is described to be such an easy and self-evident supposition, that it needs no explication or illustration to render it intelligible.

POTAMON, or POTAMO, was a philosopher of Alexandria. He steered a middle course between the scepticism of the Pyrrhonists and the presumption of the Dogmatists; but attached himself to none of the schools of philosophy of his time. He was the first projector of the Eclectic sect; for though the mode of philosophising had been pretty common before, he was the first who attempted to institute a new sect on this principle. Diogenes Laertius relates, that not long before he wrote his *Lives of the Philosophers*, an Eclectic sect, ἐκλεκτική τις ἀιρεσις, had been introduced by Potamo of Alexandria, who selected tenets from every former sect. He then proceeds to quote a few particulars of his system from his Eclectic Institutes, respecting the principles of reasoning, and certain general topics of philosophical inquiry; but from these nothing further can be learned than that Potamo endeavoured to reconcile the precepts of Plato with those of other masters.

POTASH, the lixivious ashes of certain vegetables, used in making glass, soap, and other articles. See GLASS, SOAP, and CHEMISTRY. Potash was formerly considered as a simple substance; but it appears, from the discoveries of Sir H. Davy, to be a compound of a peculiar metallic substance and oxygen.

POTATOES, of the order *solaneæ*. See BOTANY. It seems to be the prevalent opinion that potatoes were first introduced into Europe from America, by Sir Walter Raleigh, about 1586. Gerard, an old English botanist, mentions that he had reared seedlings of the potatoe in 1590, and that it grew as well in his garden as in its native soil, Virginia. Gerard gave to the potatoe the botanical name of *solanum tuberosum*,—a name adopted by Linnæus, and which it still retains. Previously to 1684, its cultivation in England was confined to the gardens of a few of the nobility and gentry. It was then first planted in the open fields in Lancashire, a county in which it is now very extensively cultivated. In an account of the household expenses of Queen Anne, wife of James I., who died in 1618, and which is supposed to have been compiled in 1613, the price of potatoes is stated at 1s. a pound.

[1] A *cent*, or hundredth part of a dollar, is about a halfpenny.

---

of the estimates on this point, the question has arisen, to what extent a corresponding increase of the post establishment must take place, both as regards the *space* in which the duties are to be performed, and the number of persons required for such performances.* The chief difficulty apprehended, is that which would be experienced in the *dispatch* of the mails from London, and other large offices, under the circumstances of the closeness of the hour of receipt to that of dispatch, to which the public are accustomed, and the great proportion of letters that are put in at the very latest hour.† On these points, the officers of the post-office, who can alone, or who can best form an opinion, while they concur in stating that a large additional expense would certainly be incurred, profess not to be able to form, or, in point of fact, not to have formed, any definite idea of its extent. The sums put to this amount in the foregoing calculations, may be considered as stated in mere conjecture; nor is it very easy to offer anything on the subject further than to observe, that any saving of time or labour, in regard to the business of dispatch, effected by Mr. Hill's plan, applies only to the taxing; partly, if at all, to the examination, and to the telling up: the duty occupying the longest time, (that of sorting) together with the stamping, being increased in full proportion to the increase of letters.

Of the minor difficulties attending Mr. Hill's plan, that which regards the mode of collecting the postage on *foreign* letters, is the most considerable. Mr. Hill seems latterly to think, that, as regards these, it might be necessary to take payment on delivery. But it seems, by no means clear, that Mr. Hill's first suggestion on that point, (namely, that of charging twopence in advance outwards, and nothing inwards) is liable to any great objection *peculiar to this part of his plan*; the persons who *send* letters abroad, being generally the same who *receive* from abroad. The inconvenience of having letters above weight, returned (after opening) from the dead letter office, cannot be allowed to stand in the way of an extensive arrangement otherwise beneficial. If parties would neither be at the pains to weigh their letters, *nor use a stamp of a penny higher price*, when in doubt, they might very fairly be left to take the consequence.

But after considering all the defects and difficulties of Mr. Hill's plan, the question recurs, if we do not adopt it, what *else* is to be done? That a *great* reduction of postage must be made, seems to be universally admitted; but what *other* scheme of reduction has been proposed, or who is ready to propose one? If we are to reduce *at all*, there seems much reason to question, whether any reduction short of that proposed by Mr. Hill, will be to good purpose. The Committee have recommended a penny rate for distances not exceeding fifteen miles, and twopence for larger distances. But there are not wanting good grounds for maintaining that the penny rate might fetch a greater revenue than the twopenny one.

Speaking loosely, it may be reckoned that, at a uniform penny postage, a fourfold increase on the general post letters, and a threefold on the twopenny and threepenny, would more than cover the charges of management. That an increase to this extent would ensue, may be held for certain; that it would ensue to double or treble this extent is, if improbable, not beyond the bounds of possibility. So that, at the worst, perhaps, the utmost evil that would arise from the adoption of Mr. Hill's plan, would be the payment of a million and-a-half of taxes in one way, instead of in another, while the vast advantage of a low rate of postage would be so much clear gain obtained. And this leads to a consideration of what, in a question of political economy, ought to be reckoned the *proper measure* of the advantage of Mr. Hill's plan. Suppose a person to pay L.1 a-year in postage, and L.5 in other taxes; suppose that in another year he pays only 5s. for postage, and L.5, 15s. in other taxes, it is evident that, *ceteris paribus*, matters will remain the same, both as regards the state and the individual, that is, if the *number of letters* which the individual gets conveyed *remains the same*. But if, on the latter supposition, he gets twenty-five letters conveyed, while on the former he only got twenty, the conveyance of the five letters additional is a clear advantage gained. The true measure then of the benefits of Mr. Hill's plan, is not the amount of surplus revenue it creates, as relative to the present, but the *number of letters conveyed, on that plan, as relative to the expense of conveyance*. If Mr. Hill, by adding twenty-five *per cent*. to the cost of conveyance, can add 100 per cent. to the number of letters conveyed, this is clear benefit. And as there can be no real advantage from the adoption of his plan that does not resolve into this principle, so (speaking on the abstract) any alleged disadvantage, not resolving into the same principle, may be regarded as only apparent.

* As regards increase of expense for *conveyance*, there does not seem so much ground for apprehension.

† Various suggestions might be offered for lessening this difficulty. For a time, at least, the system of receiving a *fee* with late letters might be extended. This would be no nullification of the boon of a cheap postage; for it would be the fairest and most convenient way of throwing the expense on those who most created it, and who could best find their account in increasing it. Or London might be split down into separate post towns, with separate bags from each, (an inconvenience that would be gradually diminishing, as railways, with *moving* offices, were established.) Or three or four different kinds of stamped covers might be sold, distinguishing by *colour*, and marked respectively, *late, later, latest*, and charged 3d., 6d., or 1s. each, to be received up to certain hours. A clerk, at the receiving box, could, with great quickness, throw out *in transition* all of the *wrong* colour for the *hour*, to wait next dispatch; or, as often as the sorting boxes are filled, their contents might be transferred to the bags.

Potatoes were not introduced into Ireland until 1610, when a small parcel was sent by Sir Walter Raleigh to be planted on his estate in the vicinity of Youghall. There is no other instance of the cultivation of an exotic having been so rapidly extended in so short a period as has elapsed since potatoes were introduced into Ireland.

Potatoes were not raised in Scotland, except in gardens, till 1728, when they were planted in the open fields by Thomas Prentice, day-labourer at Kilsyth. Prentice died at Edinburgh so late as 1792.

It has been estimated that one acre of land will produce three times, or at least twice, as much food when growing potatoes, as when employed in the culture of wheat; consequently, where the inhabitants live upon potatoes, the population will be twice or thrice as dense as where they are fed entirely on corn. While, however, the use of the potato as a principal article of food renders population comparatively dense, it tends also to render the people habitually poor, and to multiply the chances of famine. For the cultivation of the potato see AGRICULTURE. For the political views see M‘Culloch's *Commercial Dictionary*, and his notes to Smith's *Wealth of Nations*.

POTENTIA, POWER, that whereby a thing is capable either of acting or being acted upon.

POTENTIAL, in the schools, is used to denote and distinguish a kind of qualities which are supposed to exist in the body *in potentia* only; that is, to be capable in some measure of affecting and impressing on us the ideas of such qualities, though not actually inherent in themselves. In this sense we say, potential heat, potential cold, &c.

POTENTIAL, in *Grammar*, an epithet applied to one of the moods of verbs. The potential is the same in form with the subjunctive, and is, according to Ruddiman, implied in that mood, for which reason it is rejected by that grammarian; but others consider that it differs from the subjunctive by always implying in it either *possum*, *volo*, or *debeo*. It is also called the *permissive mood*, because it often implies a permission or concession to do a thing.

POTIPHAR, or PUTIPHAR, an officer of the court of Pharaoh, king of Egypt, and general of his troops, according to our translation, Le Clerc, and the version of the vulgate; but according to the Hebrew and Septuagint, the chief of his butchers or cooks. The Hebrew text, the Septuagint, and vulgate, call him Eunuch. But it is probable it in this place means only an officer of the king's court, for he was certainly married and had children. We have no other account of him but what appears in Scripture.

POTOMAC, a large river of North America, which forms through its whole course the boundary between the states of Maryland and Virginia. It rises in the Alleghany Mountains, and flowing in a north-easterly direction towards Pennsylvania, it forms a junction with the Shenandoah at Harper's Ferry, and then makes its celebrated passage through South Mountain. At its embouchure it is seven miles and a half in breadth; and at Alexandria, 290 miles from the ocean, it is one mile and a quarter in breadth. Tide-water reaches about 300 miles from the Atlantic; and for nearly that distance the Potomac is navigable for the largest vessels. The river is seven fathoms deep at its mouth, five at St George's Island, three at Swan's Point, and thence to Alexandria of the same depth. The length of its course, the curvatures included, is considerably above 300 miles.

POTOSI is the name of a department, a province, and a city of Bolivia, in South America. This part of the republic has been celebrated from the earliest times for its metallic wealth. The Cerro de Potosi, where the argentiferous mines are situated, is a conical hill, 16,037 feet in height, and about three leagues in circumference at the base. It bears marks of a volcanic origin, and its sides are marked with spots of various hues, such as dark green, orange, gray, and red. In this mountain no less than above 5000 mine mouths or levels have been opened, but very few of the mines are now worked. A tradition exists that Diego Hualca, an Indian peasant, accidentally discovered these mines whilst hunting the wild goat. In pursuing his game, he arrived at a steep declivity, and, to prevent himself from falling, he seized hold of a shrub, which, yielding to his weight, was torn from the ground, and disclosed to his eyes a large mass of silver, part of which adhered to the roots of the plant. A slave to whom he intrusted the secret of his good fortune betrayed him, and the mine was opened by the Spaniards on the 21st of April 1545. The surrounding country is also metalliferous. Silver of great fineness abounds in a hill called Guayna-Potosi (Young Potosi), close to the Cerro; but from the number of springs which occur not far from the surface, it has been found impossible to work it. The ore is pulverised in mills, driven by streamlets conducted from lakes or pools in the mountains, from one to ten miles distance from the city of Potosi. In connexion with the mines, General Miller relates the following circumstance. "A singular custom, which probably originated in the indulgence of early mine-owners, still prevails. Between Saturday night and Monday morning, the Cerro literally becomes the property of such persons as choose to work upon their own account. During that time, the boldest master would not venture to visit his own mines. They who thus take possession are called caxchas, and generally sell the produce of Sunday to their own masters. Independently of the ore thus abstracted, the caxchas did considerable mischief, by neglecting the proper precautions as they excavated. If they met with a more than usually rich vein in the course of the week, it was passed over, and cunningly reserved for the following Sunday. Very strong measures were therefore taken to abolish the custom; but every effort proved unsuccessful. The caxchas defended their privilege by force of arms, and by hurling down large stones upon their assailants." These mines are still considered the richest in South America, but great ignorance of mining operations is displayed in working them. In an agricultural point of view this province is unimportant; its riches consist in its mineral wealth.

The city of Potosi, the capital of the department, is situated on the south side of the mountain, above 13,000 feet above the level of the sea, in lat. 19° 34′ south, and long. 67° 22′ west from Greenwich. Upon the discovery of the mines, it was named an *asiento* or mine-station; but in process of time it was raised to the rank of a town, and made the capital of an intendencia. In 1611 it contained 150,000 inhabitants, according to a census taken by order of government officials. On this point General Miller judiciously observes, "This number must at that time have consisted principally of *mitayos* of every tribe existing between Potosi and Cuzco, a distance of nearly 300 leagues. Those unhappy beings were generally accompanied in their labours by their wives and families, who came rather to share in the hopeless sufferings of their husbands and fathers, than to settle in the arid hills of Potosi. It is not therefore surprising that its population should have been, by the abolition of the *mita*, and by the shocks which wealthy establishments received during the revolution, reduced to only 8000 in the year 1825."

POTSDAM, one of the provinces into which the kingdom of Prussia is divided. It is bounded on the north by the duchies of Mecklenburg-Schwerin and Mecklenburg-Strelitz, on the north-east by Pomerania, on the east by Frankfort, on the south by Saxony, on the south-west by the duchy of Anhalt-Dessau, on the west by Prussian Saxony, and on the north-west by the kingdom of Hanover. It extends over 8272 square miles, and comprehends 67 cities, or places once fortified, 16 market-towns, and 1319 villages, besides scattered houses, and distinct agricultural establishments. It is divided into thirteen circles. The population, which in 1817 consisted of 696,878 individuals, had increased in 1826 to 812,138, and has gone on augmenting up to the present time. With the exception of about 3000 Catholics, and about 2000 Jews, the whole of the inhabitants profess the Protestant religion. The land is generally level, and though tolerably cultivated, is by no means productive, though there are some local exceptions. It is provided with great natural means of access to the sea by the navigable river Havel, which falls into the Elbe, and which affords a communication between the different portions of the province. The capital of this province is the city of the same name, the first in exterior beauty in the Prussian dominions. It is situated twenty-one miles from Berlin, on an island about eighteen miles in circumference, formed by some lakes and canals, and by the river Nuthe, which here joins the Havel. Potsdam contains seven Protestant and one Catholic church, and a synagogue for the Jews. The inhabitants are about 26,000, the dwellings 1640. The civil population does not exceed 16,000 persons. The others are either military, or those employed in the fabrication of arms. The muskets for the troops are made at Spandau, but are fitted with locks and finished at Potsdam. There are manufactories carried on of silk and cotton, of leather, of cloth, of snuff, of musical and mathematical instruments, and some large breweries and distilleries.

POTTEN, a market-town of Bedfordshire, in the hundred of Biggleswade, forty-nine miles from London. It is well built now, having been burned down in 1785, after which for some time the inhabitants lived under tents. It is in a fertile district, and has a good market on Saturday. The population amounted in 1801 to 1103, in 1811 to 1154, in 1821 to 1498, and in 1831 to 1768.

POTTER, Christopher, a learned English divine, was born in 1591, and bred at Oxford. In 1633, he published his *Answer to a late Popish Plot*, entitled *Charity Mistaken*, which he wrote by special order of Charles I., whose chaplain he was. In 1634, he was promoted to the deanery of Worcester; and, in 1640, was constituted vice-chancellor of the university of Oxford, in the execution of which office he met with some trouble from the members of the Long Parliament. Upon the breaking out of the civil wars, he sent all his plate to the king, declaring that he would rather, like Diogenes, drink in the hollow of his hand, than that his majesty should want; and he afterwards suffered much for the royal cause. In consideration of this he was nominated to the deancry of Durham in 1646, but was prevented from being installed by his death, which happened about two months thereafter.

Potter, John, D.D., Archbishop of Canterbury, was the son of a linen-draper at Wakefield in Yorkshire, where he was born about the year 1674. He studied at University College, Oxford; and at the age of nineteen he published, *Variantes Lectiones et Notæ ad Plutarchi librum ad audiendis poetis; et ad Basilii Magni orationem ad juvenes, quomodo cum fractu legere possint Græcorum libros*, 1693, 8vo. In 1697, came out his edition of *Lycophron*, in folio, which is reckoned the best of that obscure writer; and soon after, he published his antiquities of Greece, in two vols. 8vo. These works established his literary reputation, and engaged him in a correspondence with Grævius and other learned foreigners. In 1706, he was made chaplain to the queen; in 1715, bishop of Oxford; and in 1737, he succeeded Archbishop Wake in the see of Canterbury, which high station he supported with much dignity until his death in 1747. He was a learned and exemplary churchman; but not of an amiable disposition, being too strongly tinctured with the pride of office. Nor is it to his credit that he disinherited his eldest son for marrying below his rank in life. His theological works, containing sermons, charges, discourses on church government, and divinity lectures, were printed at Oxford in 3 vols. 8vo, 1753.

POTTERY and Stone-ware. Under this name may be classed all those wares, from the common butter-pot mentioned by Dr Plot, to the finer kinds of earthen-ware, which, in contradistinction to porcelain, possess neither transparency nor any degree of vitrification, except on the surface after being glazed.

The most famous manufacture for this common ware, as Dr Plot states in his History of Staffordshire (1686), was at Burslem, in that county, now one of the principal towns, forming a part of that extensive and populous district called the Staffordshire potteries, in which it is calculated that no less than 30,000 persons, or one half the population, are directly employed in the manufacture of porcelain and earthen-ware. It is proved, however, that the manufacture of common wares had existed long before Dr Plot's time; but of its first introduction no tradition remains.

These common wares were made of the clays found in the district, and were of a red body covered with a glazing of lead ore, with a portion of manganese added to make a black when that colour was wanted.

About the year 1690, two ingenious artisans from Germany, of the name of Eller, settled near Burslem, and carried on a small trade for a little time. They brought into this country the method of glazing stone-ware, by casting salt into the kiln while it is hot, and some other improvements of less importance; but finding they could not keep their secrets to themselves, they left the place rather in disgust. From this time various kinds of stone-ware, glazed by the fumes of salt in the manner above mentioned, were added to the wares before made. The white kind, which afterwards became, and for many succeeding years continued, the staple branch of pottery, is said to have owed its origin to the following accident. A potter, Mr Astbury, travelling to London, perceived something amiss with one of his horse's eyes; an hostler at Dunstable said he could soon cure him, and for that purpose put a common black flint-stone into the fire. The potter observing it, when taken out, to be of a fine white, immediately conceived the idea of improving his ware by the addition of this material to the whitest clay he could procure. Accordingly he sent home a quantity of flint-stones of that country, where they are plentiful among the chalk, and, by mixing them with tobacco-pipe clay, produced a white stone-ware much superior to any that had been seen before.

Some of the other potters soon discovered the source of this superiority, and did not fail to follow his example. For a long time they pounded the flint-stones in private rooms by manual labour in mortars; but many of the poor workmen suffered severely from the dust of the flint getting into their lungs, and producing dreadful coughs, consumptions, and other pulmonary disorders. These disasters, and the increased demand for the flint-powder, induced them to try to grind it by mills of various constructions; and this method, being found both effectual and safe, has continued in practice ever since. With these improvements, in the beginning of the present century, various articles were produced for tea and coffee equipages. Soon after, attempts were made to furnish the dinner-table also; and before the middle of the century, utensils for the table were manufactured in quantity as well for exportation as home consumption.

But the salt glaze, the only one then in use for this purpose, is in its own nature so imperfect, and the potters, from an injudicious competition among themselves for cheapness rather than excellence, had been so inattentive to elegance of form and neatness of workmanship, that this ware was rejected from the tables of persons of rank; and about the year 1760, a white ware, much more beautiful and better glazed than ours, began to be imported in considerable quantities from France.

The inundation of a foreign manufacture, so much superior to any of our own, must have had very bad effects upon the potteries of this kingdom, if a new one, still more to the public taste, had not appeared soon after. In the year 1763, Mr Josiah Wedgwood, who had already introduced several improvements into this art, invented a species of earthen-ware for the table, quite new in its appearance, covered with a rich and brilliant glaze, bearing sudden alternations of heat and cold, manufactured with ease and expedition, and consequently cheap, and having every requisite for the purpose intended. To this new manufacture the queen was pleased to give her name and patronage, commanding it to be called *Queen's ware*, and honouring the inventor by appointing him her majesty's potter.

The common clays of the district are now mostly used for making the saggers or cases in which the finer wares are fired, for bricks to construct the ovens and kilns, and for some kinds of inferior wares, while the clays for the improved article are brought from Devonshire and Dorsetshire by sea to Liverpool, and by the canal to the potteries. The flint-stone is obtained mostly from London, so that it would appear the cheapness of coals has been the principal reason for the establishment of extensive potteries in this inland district, notwithstanding the heavy charges of transport on the raw materials to the seat of manufacture, and, so far as the export trade is concerned, again on the manufactured articles to the shipping ports.

Before the introduction of steam power to machinery purposes, the flint-stones were ground by water-mills at a considerable distance from the manufactories; but many of the manufacturers have now erected steam-engines of great power, for the purposes of grinding flint, and other materials used in the different processes of the manufacture.

The article of *queen's ware*, before mentioned, was composed of the Devonshire and Dorsetshire clays, mixed with a proportion of ground flint, covered with a fine soft glazing, composed of siliceous earths and carbonate or oxide of lead. This glazing, covering a very porous body, made of the above clays and a portion of flint-stone, was liable to crack or craze, and become discoloured in the using, causing a prejudice against it, under an erroneous idea that, by its coming in contact with acids and salts, the glaze had been decomposed, that the lead it contained was poisonous; and a premium was accordingly offered by the Society of Arts for the discovery of a glaze without lead, which was only cancelled on the books of the society a few years ago. It appears singular that it did not immediately occur to scientific men, that all the chemical vessels made of glass contain as large a portion of lead in their composition as there is in the glaze on queen's ware, and that the vitrification is as complete in the one case as the other. The fact is, that, through the cracks in the glazing, it was the earth composing the body of the ware which the acids and salts acted upon, leaving a coloured deposit, visible through the extreme thin lamina of glazing which covers it.

This defect in the glazing arises from several causes; the want of a corresponding contraction of the body and the glaze, from too sudden a cooling of the oven, and other mismanagement of the workmen.

Since the introduction, however, of a better clay from the mines in Cornwall (about 1777), together with a stone containing a notable quantity of feldspar, the potter has been enabled to bring his earthen-ware to a very great degree of perfection; the defect in glazing above noticed has been greatly diminished on the queen's ware, and other glazes introduced, in appearance possessing much of the texture and whiteness of porcelain, though still deficient in the solidity and compactness of the old white stone-ware which it had superseded.

About the year 1805 an article was produced called *Ironstone-ware*, in which, however, not a particle of iron stone was introduced, it being a compound principally of the Cornish materials above mentioned.

This ware has nearly all the properties of the Japan porcelain; it possesses great hardness and density; is sonorous, but is deficient in whiteness and transparency, although the vitrification is as complete as in that of the Japan. It continues to be made in great quantities, and being more durable, is perhaps, though higher in price, as economical as earthen-ware. It is a cheap substitute for porcelain, but its nature does not admit of those fine paintings and splendid decorations which are applied with so much success on that more elegant production.

Manipulation.

From the common earthen-ware to the finest porcelain, the manipulations are nearly similar. The materials being finely ground and levigated, are mixed together in their proper proportions in a liquid state, and this mixture being put into broad shallow pans or kilns, is subjected to a heat sufficient to evaporate the extra water until the clay is of a proper consistency for use, and it is then prepared by beating with wooden and iron paddles until it becomes one ductile homogeneous mass, fit for the operation of the workman. The operations of throwing on the wheel, turning in the lathe, and moulding, are similar to those already described in the article on porcelain.

Throwing.

The potter's wheel consists of a triangular bench, whereon the workman sits, having before him a small horizontal circular block on which he places the portion of clay made into a ball, according to the size of the piece of ware wanted to be made, and with his hands fashions it into the shape wanted; the inner surface being smoothed by a piece of slate, iron, or earthen-ware, cut to the form required. This workman has two assistants; one employed to prepare the balls of clay, and remove the piece when formed; the other to turn a larger vertical wheel, which gives motion to the horizontal block, or whirler, as it is called, before mentioned as being before the workman. The ware is then taken into a stove and dried sufficiently hard to be put upon the lathe and undergo the operation of turning or smoothing the outer surface.

Turning, &c.

This lathe is of the like construction as the common lathe used in wood turning, and needs no description here.

The ware is then given to another workman, who puts on the handles and feet, or such ornaments as may have to be fixed on the body of the ware; and after being thoroughly dried, it is ready for the first or biscuit firing.

It must be observed, that only articles of a circular form can be produced on the wheel or from the lathe. All others, as well as the feet and handles and ornaments, are made by different workmen, from moulds of gypsum or of baked ware. An earthen-ware called *dipped ware* is made of different colours, some of which are very striking, by being dipped into a slip or wash of the same clay, or of other clays coloured by metallic oxyds finely ground and mixed up with the wash. This operation is performed at the lathe, before the ware has had time to get dry or hard.

Firing and baking.

The ware being made dry, is placed in saggers (cases), which are piled on each other until the oven is filled up nearly to the top of the dome. Fire is then applied in mouths round the outside of the oven, having flues round the inside, and under the bottom of the oven, communicating with the mouths. The fire is applied very gradually, the operation requiring from forty-eight to fifty hours. As a test to show when the necessary degree of heat is obtained, small round caps made of common brick-clay are put into a sagger, opposite a small opening in the oven, which the fireman draws out from time to time, judging, from the degree of colour the test or trial had acquired, which was produced by the oxyd of iron contained in the clay, how to regulate his further operations.

Glazing.

The operation of glazing is similar to that detailed in the article on porcelain, but is performed with much less difficulty, and with a greater degree of certainty, on a porous than on a vitrified surface. After the ware is glazed (a considerable portion of which is first painted, and printed on the body, a biscuit), the ware is then again placed into the saggers or cases, and placed as before to undergo the second firing. In this second firing for the glazing, a much lower degree of heat is applied than for the biscuit-ware, and the operation is performed in fifteen or eighteen hours, according to the size of the oven. The painting or enamelling, and the printing on earthen-ware, are done in the same manner as that described on porcelain, which need not here be repeated.

The extent to which the manufacture of pottery wares is now carried on in this country, in which porcelain may be included, together with its usefulness and excellence, has rendered it a subject of great national importance. The raw materials are of home production, and of little intrinsic value, the transport of which affords to the coasting trade a freightage of from 40,000 to 50,000 tons annually. The manufactured articles are wholly produced by manual labour, which is not likely to be superseded by machinery, while the export of the bulky article of earthen-ware to all parts of the world gives employment, to an immense extent, to the shipping of this and other countries. Nor is this interesting manufacture without some claim in furthering the progress of the fine arts, by the cultivation of painters, engravers, and modellers, many of whom have displayed talents of a superior order in their respective lines. In flower-painting, the specimens exhibited in the work of English artists cannot be excelled. In figure-painting, owing to the want of schools for design, the porcelain painters of this country have not made much progress; but in flower-painting, and in decoration generally, our British artists cannot be surpassed.

There are some considerable manufactories of pottery ware in the north of England, and one or two in Yorkshire; but the principal site of both pottery and porcelain wares is in the newly created borough of Stoke-upon-Trent, which contains a population of nearly 60,000 persons, engaged either directly or indirectly in these manufactures. On the passing of the reform bill, this borough was considered of sufficient importance to have its great interests represented by two members in parliament. (B. A.)

POULTON, a market-town in the county of Lancaster, and hundred of Amounderness, 235 miles from London. It is on the sea-shore, near the mouth of the river Wye, and communicates by a canal with most of the rivers of the county. It has a market on Monday. The population of the town was, in 1801, 769; in 1810, 926; in 1821, 1011; and in 1831, 1025; but the whole parish contains five townships, and at the last census 4080 inhabitants.

POULTRY, all kinds of domestic fowls brought up in yards, as cocks, hens, and the like. See Agriculture.

POUND, a standard weight, for the proportion and subdivisions of which, see the article Weights and Measures.

Pound also denotes a money of account, so called because the ancient pound of silver weighed a pound troy.

POUNDAGE, a subsidy of twelve pence in the pound, granted to the crown on all goods and merchandises exported or imported; and if by aliens, one penny more.

POUSSIN, Nicholas, an eminent French painter, born in 1594, at Andel, a little city in Normandy, where his father was of noble extraction, but born to a small estate. Being invited to Paris by Louis XIII., who assigned him a pension and lodgings in the Tuilleries, he painted for Prince Justiniani an historical picture representing Herod's cruelty; an admirable composition, in which he gave such expression to every character, as could not fail to strike the beholder with terror and pity. He then laboured for several years on the celebrated pictures of the seven sacraments of the Catholic church. But none of Poussin's designs have been more generally admired than that of the death of Germanicus, which would have gained him immortal honour if he had never painted another picture. He began the labours of Hercules in the gallery of the Louvre; but the faction of Vouet's school railing at him and his performances, put him so out of humour with his own country, that he returned to Rome, where he died in 1665. He never went beyond easel-pieces, for which he had a perpetual demand; and his method was to fix the price he expected on the back of the canvass, which was readily paid.

Poussin, *Gaspar*. This painter, whose real name was *Dughet*, was born at Paris in 1600, and was induced to travel to Rome, not only from a love of the art of painting, but also to visit his sister, who was married to Nicholas Poussin. Sandrat says that Gaspar was employed at first only to prepare the pallet, pencils, and colours for Nicholas; but by the precepts and example of that excellent master, he gradually rose to the highest reputation, and is undoubtedly one of the best landscape painters that ever appeared. Whilst he continued at Rome he dropped his own name, and assumed that of his brother-in-law and benefactor, by which only he is now known. He died in 1662.

POUTEOU, or Pootoo, a small island off the coast of China, a little to the east of Tehnsan. It is represented as a beautiful spot, containing numerous temples.

POVERTY Bay, on the east coast of New Holland, in the South Pacific Ocean, discovered by Captain Cook in 1769. Long. 181. 36. W. Lat. 38. 42. S.

POWALLY, a town of Hindustan, in the province of Tinnevelly, twenty miles south-west from Madura. Long. 77. 59. E. Lat. 9. 39. N.

POWANGHUR, a celebrated hill-fort of Hindustan, province of Gujerat. It rises nearly perpendicular to the immense height of six hundred yards, and is inaccessible except on the north side, which is fortified with fine walls. A small rock rises on the summit, on which stands a Hindu temple. It was taken by the British, after a very slight resistance, in 1803. Long. 73. 39. E. Lat. 22. 31. N.

PRACELS, a range of small islands and rocks in the Chinese Sea, about sixty miles to the east of Cochin-China. They are of dangerous navigation, from the currents that run between them. Length, 300 miles; breadth, 60; from long. 110. to 111. E. and lat. 11. 40. to 16. 10. N.

PRÆMUNIRE, in *English Law*, a writ of citation.

PRÆNESTE, in *Ancient Geography*, a town of Latium, to the south-east of Rome, towards the territory of the Æqui. It is a place of great strength, and famous for the temple and oracle of Fortune, called *Sortes Prænestinæ*.

PRAGMATIC SANCTION, in the civil law, is defined by Hottoman to be a rescript or answer of the sovereign, delivered by advice of his council, to some college, order, or body of people, upon consulting him on some case of their community. The like answer given to any particular person is called simply rescript.

The term pragmatic sanction is chiefly applied to a settlement of Charles VI. emperor of Germany, who, in the year 1722, having no sons, settled his hereditary dominions on his eldest daughter, the archduchess Maria Theresa, which was confirmed by the diet of the empire, and guaranteed by Great Britain, France, the States-General, and most of the powers in Europe.

PRAGUE, a city, the capital of the Austrian kingdom of Bohemia. It is nearly in the centre of the kingdom, on the river Moldau, which runs to the Elbe on its way to the ocean, and divides the city into two parts. There is over the river one of the finest ancient bridges in Europe, 1800 feet in length, consisting of sixteen arches, and adorned with twenty-eight statues of saints and martyrs.

The city is built on seven hills, and the streets are consequently irregular; the houses are very antique and large, and the compass of the whole is said to be nine miles. It contains numerous public buildings, amongst others the metropolitan cathedral, dedicated to St. Beit, with twelve highly-decorated side chapels, besides which, are no less than forty-six other Catholic churches, and several monasteries and nunneries. The palace of the ancient kings of Bohemia has been converted into a citadel; but a more modern one, now used as a Stadthouse, is of vast extent, containing 150 apartments, with a hall near equal in size to that of Westminster. There is a university, one of the oldest in Germany, in which degrees are obtained in the four faculties of law, medicine, theology, and philosophy. It has connected with it a library of 100,000 volumes; a botanic garden, an astronomical observatory, and collections of natural history. There are forty-four professors, and the students, which were in 1816, only 8798, had increased, and in 1823, were 1348. This seminary may be considered the birthplace of the reformation of religion, as John Huss and Jerome exercised in it the right of free inquiry, and became victims to it nearly one hundred years before the appearance of Luther. There are also several societies for the promotion of learning, of the sciences, and of the fine arts. The institutions for the maintenance of the poor, for affording medical aid, and for other benevolent purposes, are numerous and well conducted. The inhabitants, like those of all Europe, have greatly increased since the treaty of Vienna in 1815. In that year they were 67,730 Christians, and 6,783 Jews; in 1817, they were 79,606, from which, by regular increase, they had grown up, in 1827, to 107,325.

The chief trade is that which arises from its central position, and from its being the seat of the local government; but there are manufactures of gold, silver, jewellery, and other luxuries, as well as others, for internal consumption, of silk, cotton, linen, and woollen goods, and for cutlery and haberdashery wares; there are also large breweries and distilleries. The city is fortified; but, from being commanded by hills, is scarcely defensible; but it has been the theatre of many bloody actions. A battle was fought in 1620 on the white plains a few miles from the city, between the Elector Palatine and the Austrians, when the success of the latter caused the independence of Bohemia to expire. It was besieged by the French in 1751, and by the Prussians, who bombarded it in 1757; but in both cases the resistance was attended with success. Lat. 50. 5. 33. Long. 14. 49. 40.

PRAAM, a kind of lighter used in Holland and the ports of the Baltic sea, to carry the cargo of a merchant-ship alongside, in order to lade or to bring it to shore to be lodged in the storehouses after being discharged out of the vessel.

PRATINAS, a Greek poet contemporary with Æschylus, and born at Phlius. He was the first amongst the Greeks who composed satires, which were represented as farces. Of these, thirty-two were acted, as also eighteen of his tragedies, one of which only obtained the poetical prize. Some of his verses are extant, quoted by Athenæus.

PRATO, a city of the duchy of Tuscany, in Italy, the capital of a district called a vicarate, of the same name, in the circle of Florence. It stands on the river Bisenzeo. It is surrounded with walls and ditches. It contains some handsome plazas, a theatre, a cathedral, twelve parish and seventeen monastic churches, four hospitals, and 10,000 inhabitants, who make linen and woollen cloths, paper, copper ware, and other articles, and draw from quarries some good millstone.

PRATT, CHARLES, Earl of Camden, was the third son of Sir John Pratt, knight, chief-justice of the Court of King's-Bench under George I. by his second wife Elizabeth, daughter of the Reverend Hugh Wilson, canon of Bangor, and was born in 1713, the year before his father was called to the honour of the bench. He received the first rudiments of his education at Eton, and afterwards removed to King's College, Cambridge. Of his early life at both places little is known, other than that at college he was found to be remarkably diligent and studious, and particularly so in the history and constitution of this country. By some he was thought to be a little too tenacious of the rights and privileges of the college he belonged to; but perhaps it was to this early tendency that we are indebted for those noble struggles in defence of liberty, which, whether in or out of office, he displayed throughout the whole course of his political life. After remaining the usual time at college, and taking his master's degree, in 1739 he entered himself a student of the Inner Temple, and was in due time admitted by the honourable society as a barrister-at-law. And here a circumstance developes itself in the history of this great man, which shows how much chance governs in the affairs of this world, and that the most considerable talent and indisputable integrity will sometimes require the introduction of this mistress of the ceremonies, in order to obtain that which they ought to possess from their own intrinsic qualifications.

Mr. Pratt, after being called to the bar, notwithstanding his family introduction, and his own personal character, was very near nine years in the profession, without ever getting in any degree forward. Whether this arose from a natural timidity of constitution, ill-luck, or perhaps a mixture of despondence growing out of the two circumstances, it is now difficult to tell. But the fact was so; and he was so dispirited by it, that he had some thoughts of relinquishing the profession of the law, and retiring to his college, where, in rotation, he might be sure of a church living, that would give him a small but honourable independence. With these melancholy ideas he went as usual the western circuit, to make one more experiment, and then to take his final determination. Mr. Henley, afterwards Lord Northington, and chancellor of England, was in the same circuit. He was Mr. Pratt's most intimate friend; and he now availed himself of that friendship, and told him his situation, and his intentions of retiring to the university and going into the church. He opposed his intention with strong raillery, and got him engaged in a cause along with himself; and Mr. Henley being ill, Mr. Pratt took the lead, and displayed a professional knowledge and elocution that excited the admiration of his brother barristers as much as that of the whole court. He gained his cause; and besides, he acquired the reputation of an eloquent, profound, and constitutional lawyer. It was this circumstance, together with the continued good offices of his friend Henley, which led to his future greatness; for with all his abilities and all his knowledge, he might otherwise in all probability have passed his life in obscurity, and gone down to the grave unnoticed and unknown.

He now became one of the most successful pleaders at the bar, and honours and emoluments flowed thick upon him. He was chosen to represent the borough of Downton, Wiltshire, after the general election in 1759; recorder of Bath 1759; the same year he was appointed attorney-general; and in January 1762 he was called to the degree of serjeant at law, appointed chief-justice of the common pleas, and knighted. His lordship presided in that court with a dignity, weight, and impartiality, never exceeded by any of his predecessors; and when John Wilkes was seized and committed to the Tower on an illegal general warrant, his lordship, with the intrepidity of a British magistrate, and the becoming fortitude of an Englishman, granted him an *habeas corpus*, and on his being brought before the court of common pleas, discharged him from his confinement in the Tower, 6th May 1763, in a speech which did him honour. His wise and spirited behaviour on this remarkable occasion, was so acceptable to the nation, that the city of London presented him with the freedom of their corporation in a gold box.

On the 16th of July 1765 he was created a peer of Great

Britain, by the style and title of Lord Camden, Baron Camden, in the county of Kent; and, on the 30th July 1766, on the resignation of Robert Earl of Northington, he was appointed lord high chancellor of Great Britain. In this capacity he, in a speech of two hours, declared, upon the first decision of the suit against the messengers who arrested Mr. Wilkes, that it was the unanimous opinion of the whole court, that general warrants, except in cases of high treason, were illegal, oppressive, and unwarrantable. He conducted himself in this high office so as to obtain the love and esteem of all parties; but when the taxation of America was in agitation, having declared himself against it, and strongly opposed it, he was removed from his station in 1770.

Upon the fall of Lord North he was again taken into the administration, and on the 27th of March 1782, appointed president of the council; an office which he resigned in March 1783. On the 13th of May 1786, he was created Viscount Bayham of Bayham Abbey, Kent, and Earl Camden. He died on the 18th of April 1794 at his house in Hill Street, Berkeley Square, being at that time president of his Majesty's most honourable privy council. He married Elizabeth, daughter and co-heir of Mr. Nicholas Jeffery, son and heir of Sir Jeffery Jefferys of Brecknock Priory, knight, who died in December 1779, and by whom he had issue John Jefferys Pratt, born 1759, and several daughters.

PRASLIN, an island in the eastern seas, one of the group called the Sechettis. It contains an excellent harbour, well sheltered by small islands from every wind. The interior is lofty, and covered with trees. Long. 55. 47. E. Lat. 4. 19. S.

PRATUS ISLES, a cluster of islands, shoals, and large rocks, in the Chinese sea, about 300 miles S.S.E. of Canton. The principal island, called Prata, is surrounded by a very extensive shoal of uncertain extent. They are six leagues in extent from north to south, and stretch three or four leagues to the east. Long. 116. 45. E. Lat. 23. 50. N.

PRAXAGORAS, a native of Athens, who, at nineteen years of age composed the History of the Kings of Athens, in two books; and at twenty-two wrote the Life of Constantine the Great, in which, though a pagan, he speaks very advantageously of that prince. He also wrote the History of Alexander the Great. Praxagoras lived under Constantine, about the year 345.

PRAXITELES, a very famous Greek sculptor, who lived 330 years before Christ, during the reign of Alexander the Great. All the ancient writers mention his statues with high commendation, especially a Venus executed by him for the city of Cnidus, which was so admirable a piece, that Nicomedes offered to release the inhabitants from their tribute as the purchase of it; but they refused to part with it. The inhabitants of the isle of Cos requested of Praxiteles a statue of Venus; and in consequence of this application the artist gave them their choice of two, one of them representing the goddess entirely naked, and the other covered with drapery. Both of these were of exquisite workmanship. Although the former was esteemed the most beautiful, nevertheless the inhabitants of Cos had the wisdom to give the preference to the latter, from a conviction that no motive whatever could justify their introducing into their city any indecent statues or paintings, which are so likely to inflame the passions of young people, and lead them to immorality and vice.

PRAYER, a solemn address to God, which, when it is of any considerable length, consists of *adoration*, *confession*, *supplication*, *intercession*, and *thanksgiving*.
